There are a number of instructional design models available to use in the development of an instructional environment (e.g., Gustafson & Branch, 1997). They provide a guide for the developer to use in creating a meaningful experience for the learners. While we relied on the general assumptions of instructional design including the need to create a learning environment that is effective, efficient, and motivating (Smith & Ragan, 1999), we developed our own framework of instructional design, borrowing from a number of sources, as we moved forward in the design and development cycle. In this way, we have been able to use approaches that are context-specific – that is, we have been able to develop a model that allows us to respond to the needs of our particular learners. To this end, we have relied on three key instructional design approaches: formative evaluation, needs assessment, and rapid prototyping. In our work thus far, the pilot workshops have provided us with an opportunity to do formative evaluation as we are provided with an opportunity to consider the intervention (the InterMath experience) and determine what revisions are needed (Seels & Glasgow, 1998). We have used needs assessment frameworks in our analysis of the formative evaluation data to identify the critical needs of the learners (Kemp, Morrison, & Ross, 1998). And, we have implemented a rapid prototyping approach in developing the hints system (Tripp & Bichelmeyer, 1990). Every facet of our work has been tightly linked to teacher needs and teacher feedback, thus our decision to view our efforts as responsive design. Further, as will be discussed, most of our design effort has arisen out of learning and motivational principles, therefore, we characterize the approach we are taking to this facet of InterMath development as principled, responsive design.

### **Formative Evaluation**

The purpose of formative evaluation is to determine what revisions are needed in order to optimize learning in a given instructional setting (Seels & Glasgow, 1998).

We had the opportunity to pilot test InterMath two times in 2001 allowing us to collect formative evaluation data. These data were collected during each InterMath session in each workshop through both formal and informal means. InterMath instructors and facilitators observed the teachers each week in the workshop as they worked on a variety of mathematical problems. Fieldnotes and written reflections were completed in each of the classes. In addition, many participants (eight in one class and all four teachers who completed the second pilot) were interviewed at the conclusion of the workshops and all participants were surveyed both at the beginning and the end of the workshop. These data provided information regarding difficulties the workshop participants experienced and how the InterMath experience could be changed to better benefit teachers in future workshops.

An analysis of the data collected provided insight into participant frustrations over the difficulty of many InterMath investigations. Some of the participants noted that they do not have strong backgrounds in mathematics, while others described the mathematical 'rustiness' that has occurred while teaching middle-grades math. These comments gave sufficient cause to consider creating some type of mathematical scaffolding system for the InterMath workshop, as InterMath personnel are not always on hand when the teachers are working on their investigations. Further, our observations showed that the teachers struggled, at times, to use the technology. While the most evident problems were with webpage development software, we also noted many occasions when the teachers were unable to use tools such as Geometer's SketchPad (GSP) without assistance.

Using instructional design principles, we determined that some form of computer-based scaffolding system would be beneficial for teachers participating in InterMath. The goals of this system would be to encourage teachers to select problems that are more difficult than those they might otherwise attempt, thereby assisting them in furthering their mathematical thinking and understanding, and decrease the frustration that can occur when they come to a point where no more progress can be made without some type of assistance.

### **Needs Assessment**

The goal of the needs assessment is to identify particular needs associated with completing a job or task (Kemp, Morrison, & Ross, 1998). In our case, the needs assessment focused on helping us understand what the teachers were unable to do or had to struggle with in order to succeed in the workshop. The first phase of our needs assessment focused on defining some of the critical needs of our participants. It became apparent that the teachers needed more support than could be offered in the workshop and because our team could not be available all the time, we decided that an online system to support teacher learning anytime, anywhere was a critical element of the support system. One clear goal we had was to maintain a balance between providing too little and too much support to the teachers. Our concern was that the hints

– whether for GSP or mathematical problems solving – not only helped the teachers achieve their goals, but also engaged them in thinking about the mathematics they were working with. We realized that by adding a “hint” to the more complicated problems, we may be able to aid teachers in persevering to become more successful problem-solvers. These hints may focus on the mathematics or on the use of technology to support the mathematics.

One of our primary concerns in considering a support system was that it may inadvertently limit the cognitive growth potential for users of InterMath. Based on our initial field test of the hints, this concern was well-founded. Teachers in our test group clicked on the hint before they attempted to solve the problem on their own. The static hint system cannot provide the cooperative problem-solving effort between the learner and a more knowledgeable other that defines scaffolding (Collins, Brown, & Newman, 1989), nor can it anticipate exactly when the learner may require assistance. Additionally, our learners would need to take responsibility for “fading” the scaffolding. It is unclear that learners can effectively self-monitor to determine where they are in their own ZPD (Vygotsky, 1978), however, this is a critical part of the scaffolding fading process (Kao & Lehman, 1997; Oliver & Hannafin, 2000). Further, learning in this environment comes from engagement in the problem-solving process, therefore the learners need to be actively involved in the process in order to benefit. If they click on the hint before struggling on their own, the potential of the learning experience may be significantly weakened.

As we continued working in the design and analysis phase of this undertaking, we began to consider the purpose of the hints. We identified three distinctly different purposes hints might serve: hints as motivators, hints as models of expert thinking, and hints as generalizable strategies. We also discussed why there may be good reason to include no hints at all.

### **No Hints**

The “no hints” argument arose from our beliefs about learning and our previous work with teachers supporting students in computer-based environments (e.g., Hawley & Duffy, 1998). As mentioned previously, we were concerned about the ability of an online scaffolding system to provide the kind of help the learner needed at the time she needed it. After all, the online system cannot sense where the learner is within a problem, what the learner’s mathematical knowledge is, or whether the problem is a technical one (e.g., not knowing how to construct a shape or write a formula) or a mathematical one (e.g., not knowing how to approach a problem). It was the “inside help” that we felt the system could not provide (Polya, 1981). That is, the computer is not sensitive or “intelligent” enough to provide the learner with the kinds of questions or suggestions that may have occurred to the student – and those are the questions that move the student to new levels. Further, the static hints system is problematic in that scaffolding should be an interactional approach (Driscoll, 1994). It, ideally, provides

for an interaction between two people that can evolve and/or fade over time. The reciprocal teaching research (e.g., Palincsar & Brown, 1984) provides a compelling description of a scaffolding system that exemplifies this approach. Our online system could not be like this. Our design team considered how or if the hint system could serve as a scaffolding device without this kind of teacher-learner interaction.

While compelling, the arguments against the hints system did not provide alternatives for supporting teachers in attempting or completing the problems that offered the most promise for their mathematical development – the “hard” math problems.

### Approaches to Hints

Polya’s four-step problem-solving process (Polya, 1957) provided a basis for our thinking about hints as generalizable strategies. We determined that our hints would be most productive if focused on the first two parts of the process: (1) Understand the problem and (2) Devise a plan. To this end, we explored the development of a set of hints that provided both the strategy (e.g., “Can you restate the problem?”) and a specific hint for the problem of interest (e.g., “Before you answer the given problem, think about the definitions and formulas of circumference and area. On what part of each circle do you really need to focus? How do these parts relate to each other?”).

We also explored expert thinking as another foundation for the hint system. Wood, Bruner, and Ross (1976) define the expert’s role in scaffolding as directing and maintaining the learner’s attention, while also modeling the task and highlighting the critical features of that task. We considered the fundamental differences in expert and novice organization of knowledge (e.g., Bransford, Brown & Cocking, 1999). Experts tend to organize thinking and strategies around core concepts and more readily see where to apply concepts whereas, novice thinkers tend to exhibit signs of more linear and procedural understandings. Modeling has been shown to be an effective means for supporting the development of expert thinking (e.g., Palincsar & Brown, 1984; Schoenfeld, 1991). Our primary concern was if learners do not engage in reflective adoption and adaptation of the modeled example, they learn only a prescriptive task rather than a generalizable approach. With this hint system, supporting the learner’s reflection would be one way to move toward the benefits of the modeling system.

Finally, we looked at the motivational aspect of the hints. We recognized the importance of providing indirect facilitation for goal attainment, rather than controlling learners’ actions (Ford, 1992). In our case, the hint system would be the determining factor for whether they chose a more challenging problem over a simpler one. We felt that, along with the motivational boost, there would also be a teaching self-efficacy boost from this system (e.g., Bandura, 1989; Pajares, 1996). It was our hope that providing the system would increase learner’s feelings of self-efficacy, increasing their likelihood of expanding their mathematical horizons.

Once we had considered all the evidence and the development issues involved with the various hint system formats, we began working toward developing a system

that attempted to support mathematical development by relying on questions and examples that are readily transferred to other mathematical situations. To achieve this, the mathematical hints systems uses only questions the learners will be able to use on other problems and in other ways (Polya, 1981). In this way, we aimed to develop tools that, while static, might support the development of transferable knowledge for the learner.

A critical and ongoing effort in our design and development phase has focused on the identification of investigations most in need of hints and what kinds of hints they might need. This process was begun by having a new graduate student whose mathematical background was similar to our target audience's work several of the investigations to identify places where they became difficult as well as ways she was able to overcome those difficulties. This provided a beginning guide for the hints system. However, her activity on the project team and in graduate-level mathematics education courses quickly moved her beyond the mathematical content knowledge of our target audience. We are currently exploring new strategies for determining which investigations require more support.

To better understand what a static, computer-based hints system might look like, we explored existing systems to see how they provided support for learners. These systems included the support system in the Knowledge Integration Environment (WISE or KIE) (Slotta & Linn, 2001), as well as EMILE (Guzdial, 1994) and CSILE (Scardamalia et al., 1992). These tools provided very different approaches to scaffolding learning, ranging from static to very dynamic and including various levels of teacher/knowledgeable other support within the system.

The tools that we reviewed ranged, also, from technologically complex to those that were relatively simple. In the end, the decision to follow a simpler path was tied to two issues: budget and time. The enormous undertaking of developing a dynamic support system was outside the scope of our efforts and was not included in the budget. Further, InterMath is a multifaceted system that includes communications tools, a dictionary, materials for instructors, and, of course, investigations. Because each of these pieces requires support, the need to keep the scaffolding system to a manageable size was considerable. Further, the InterMath team recognized that teachers in need of more specialized support could contact an InterMath team member or could use the communications tools to pose questions to other members of the community. The trade-off with this was the loss of momentum caused by the delayed communication in an asynchronous environment. However, if we paired a just-in-time scaffolding system with these other tools, we felt we could offer support for the learners that would be meaningful.

The most critical decision made as a result of our process was the decision to split the hints system into two distinct pieces. One piece would be the hints as discussed in the analysis section. The other part would be the "Constructionary," which is a

system to support teachers in completing mathematical constructions using Geometer's Sketchpad. While making constructions in this program is still a mathematical process, it is the point where mathematical concepts intertwine with technology. The support that teachers struggling with the technology needed was not the same kind of support they needed to conceptually understand the problem.

The Constructionary borrows heavily from the Lego™ approach to instruction – teachers are provided with pictures that show the construction being put together. They are provided with minimal text as well because our rapid prototyping process indicated that the images alone were too confusing. The goal of the Constructionary is to provide teachers with the support they need, while forcing them to remain engaged in the mathematics of the construction. In the development of the Constructionary, we have relied on the principles of rapid prototyping (Tripp & Bichelmeyer, 1990). As we develop constructions to be included in the Constructionary, we show people who are like our target audience the hint. Then, we ask them to decipher what they think that hint is trying to show. The data gathered are used to immediately alter the hints to optimize their effectiveness.

For the content-specific hints system, we chose to use the scaffolding system in WISE (Slotta & Linn, 2001) as our key model. It is a hints system that provides hints on command. A single process step may have more than one hint, but only one appears at a time. The users, in this case middle school students, must click to request a second hint. Further, the hints point the users back to information or processes they have already worked with. As a scaffolding system, the WISE approach aims to develop student inquiry skills.

### **Rapid Prototyping**

The instructional design and development process is ongoing. Our design process has run parallel to our evaluation process and has taken a variety of forms. The analysis and design phases have thus far employed three instructional design strategies: 1) having a person similar to our target audience work through investigations to identify potential problems and discuss how those complications affect the successful completion of the problem; 2) reviewing existing computer-based scaffolding systems to explore the characteristics and possibilities of effective systems; and 3) working with subject matter experts on our team to determine how to translate face-to-face questioning strategies to static online strategies. Further, as we move into the development phase we are using a fourth key strategy – rapid prototyping.

Rapid prototyping is an approach to instructional design in which the product is created in a minimal form in sequential iterative cycles so that it can be evaluated by target users. In our case, we have developed three separate rounds of paper-based Constructionary entries to determine how much text is necessary to convey our meaning while still maintaining cognitive engagement on the part of the user. Further, we have conducted one mock-up version of two of the hint types to determine teacher reaction

to them. This approach allows a responsive design system to emerge that constantly relies on feedback and input from the end-users. Further, rapid prototyping allows developers the opportunity to evaluate ideas before considerable time and money have been spent in their creation. As we move forward with our ideas, we will begin to move away from rapid prototyping and will turn again to formative evaluation simply because we now need to do some full-scale development which does not lend itself to the iterative rapid development processes.

### **Moving Ahead**

Both the Constructionary and the content hint system have gone through multiple rapid prototyping iterations. Even as early in the process as the pilot courses, we were able to bring in different kinds of hints and test them out with members of our target audience. This provided valuable feedback as we were able to put the hints system to work, watch the users interact with it, and talk to them about their reactions to it. Interestingly, in the first test of the hints strategies, the participants claimed that the hints were not useful, despite having relied on them to complete their problems.

We are currently involved with the development stages of both the content hint system and the Constructionary. There are still obstacles to overcome, including making the final decisions about which approach to the content hints system to adopt. There are very practical considerations that must be weighed in this decision. For example, we must choose a hints system that members of our team can create without the need for extensive work on any one problem. This has been a critical factor in our exploration of hints approaches.

Another critical obstacle is determining which investigations need hints and what kinds of problems teachers might have with them. This is problematic because all of our team members have either extremely high mathematical ability, or mathematical ability that is too limited. To address this problem, we have considered a number of approaches including conducting more teacher observations during our next workshop offering and using our best guesses to find problematic investigations.

### **Conclusion**

The purpose of this paper was to explore the issues and approaches being used to develop a dual-purpose hint system in response to user needs in the InterMath workshop. Thus far, we have included users in every aspect of the development. We watched them struggle and spoke to them about difficulties to identify the original need, we have worked with them to refine our scaffolding ideas, and we will continue to work with users as we develop and implement the system. Our position is that this is a powerful approach to instructional design as it allows instructional tools to be developed that support learners in the process of learning.

## CHANGES IN MATHEMATICS TEACHING: A CAREER PERSPECTIVE

Paola Sztajn  
University of Georgia  
psztajn@coe.uga.edu

This report addresses issues of teacher change over time. It presents factors that, from the teachers' point of view, were important in the establishment of their ways of teaching mathematics to young children. The project involved 5 elementary school teachers with ages between 45 and 60, all with over 20 years of teaching experiences. It focused on the stories the teachers constructed about their careers as they reflected upon their professional trajectories. Analyzing data from one of the participating teachers, Sharon (pseudonym), teaching appears as job that is impregnated with changes. Sharon presents the development of her mathematics teaching as a continuous search process that has gone through many phases and incorporated many recommendations for change. In Sharon's stories, educational trends in general, and new recommendations for school mathematics in particular, have promoted changes in her mathematics teaching. Her school environment, her colleagues, and the professional development activities in which she participated appear as main change agents in Sharon's professional story.

The publication of the *Curriculum and Standards for School Mathematics* (National Council of Teachers of Mathematics [NCTM], 1989) in the late 1980s strengthened mathematics educators concern with teacher change. The constructivist perspective that underlined the document implied a vision of mathematics teaching that greatly differed from the widespread teaching model in which teachers hold and transmit knowledge to students. For many teachers, aligning their instruction with the vision espoused by the council represented a new and demanding challenge. In this context, studies of mathematics teachers' change thrived.

Four positions on the process of change in mathematics teaching developed in the late 1980s: a Piagetian stand, an approach rooted in cognitive science, a socioconstructivist perspective, and a view based on teachers' knowledge of mathematics itself (Nelson, 1997, p. 4). Despite their differences, the four theoretical positions pointed to the fact that transforming mathematics teaching was not a simple process. Rather, for most teachers, it required ongoing effort and support. Recent studies have shown that despite a history of resistance to change, teachers can successfully incorporate NCTM's suggestions into their mathematics teaching practices (e.g., Ferrini-Mundy, Graham, Johnson, & Mills, 1998). Thus, mathematics education researchers have come to perceive change in school mathematics as a difficult but feasible process.

This paper discusses change from the teachers' perspective. In particular, it addresses the ways in which teachers portray change in their professional stories. How do teachers perceive their own professional changes? What are factors they consider as catalysts for change? Analyzing data from Sharon (pseudonym), one learns that

teaching is a dynamic job, impregnated with changes. Sharon presents the development of her mathematics teaching as a continuous search process that has gone through many phases and incorporated many recommendations for change. In Sharon's stories, educational trends in general, and new recommendations for school mathematics in particular, have indirectly promoted changes in her mathematics teaching. Her school environment, her colleagues, and professional development opportunities appear as main change agents in Sharon's professional story.

### **Framework**

An epistemology of professional practice is needed for the comprehension of elementary school mathematics teaching. Tardif (2000, p.13) defined this epistemology as the study of the set of knowledge used by professionals in their everyday working space to accomplish all their tasks. This epistemology is charged with revealing teachers' content-knowledge, attitudes, and know-how, as well as the ways in which these different factors are combined and used in teachers' performance of their professional duties. From this perspective, teachers' knowledge is personal, situated, and time dependent. It relies on teachers' life histories and develops throughout their careers. Tardif and Raymond (2000) proposed that to understand teaching, one should investigate the history of development of teachers' personal knowledge base for teaching. It is necessary to understand teachers over time, asking them about the history of their knowledge and practice.

Within this perspective, this project studies teacher change over time. It looks for changes teachers embrace as they experience their lives in the classroom. The study is based on teachers' own explanations for their mathematics teaching and for their accomplishments over the years. In particular, it explores factors that, from the teachers' point of view, are important in the establishment of their ways of teaching mathematics to young children. It searches for factors that, over the span of the teachers' careers, served as catalysts for change.

The study of teachers requires a methodological approach that allows for the representation of action; an approach that can cope with the many ambiguities and dilemmas that emerge from experiences in the classroom. This project uses narratives to study teachers. A narrative is a "symbolic presentation of a sequence of events connected by subject matter and related by time" (Scholes, 1981, p. 205). Narratives are "the closest we can come to experience" (Clandinin & Connelly, 1994, p. 415). In education, narrative inquiry presents teachers' stories while searching for patterns of understanding. Stories are the phenomena under study and narratives offer a way to studying them (p. 416).

A story is made of organized information. Humans seek to provide a sense of coherence for their experiences and arrange their life episodes into a meaningful story (McAdams, 1993). They bring together different parts of their selves to compose a convincing story that illustrates essential truths about them. This patterned integration

of “remembered path, perceived present, and anticipated future” (p. 12) allows individuals to construct the stories that make them unique. These stories are more about meaning than they are about facts. “In the subjective and embellished telling of the past, the past is constructed” (p. 28). People’s self-stories are particularly important in mid-life. At this point, many face the challenge of recreating their identities to enhance their “sense of unity and purpose in life” (p. 202). “In mid-life we endeavor to put many pieces of our life story together into a more integrative and generative whole” (p. 220).

Looking at teachers between the ages of 40 and 50-55 years of age, Sikes, Measors, and Woods (1985) reported that this is a time when teachers come to terms with where they are in life, assessing what they have and have not achieved. Despite the frailty of the assessment moment, many teachers during this stage recognize their knowledge and experience. They feel respected and proficient (p. 229). Within teachers’ professional cycles (Huberman, 1993), those with 4 to 6 years of teaching typically experience a feeling of stabilization and of consolidation of their pedagogical repertoire. Following that, between 7 and 25 years of experience, teachers may either attempt to diversify their practices, enlarging their professional repertoire and searching for new challenges, or they may go through a reassessment phase in which they question their path. Teachers in the diversification path can be highly motivated and engaged. Those who experience reassessment face a period of self-doubt and a sense of routine. After 25 years of teaching experience, many teachers achieve serenity, a feeling of greater confidence and acceptance of who they are.

Teachers’ professional personal stories and their organization of experiences over many years in the classroom are the kernel of this study. The project involved 5 elementary school teachers with ages between 45 and 60, all with over 20 years of teaching experiences. It focused on the stories the teachers constructed about their careers, as they reflected upon, structured, and organized their own trajectories. Working with very experienced teachers offered the possibility of looking back to life in the classroom in order to pinpoint important events and influences that marked the teachers careers. It allowed teachers to talk about different changes they made over time.

Situating teachers’ personal stories within school contexts, one needs to consider that, at schools, teachers live in two fundamentally different spaces: one where they are with students behind the classroom door, and another where they are with their peers (Clandinin & Connelly, 1996). Outside the classroom is a space “filled with knowledge funneled into the school system for the purpose of altering teachers’ and children’s classroom lives” (p. 25). Clandinin and Connelly call sacred the stories that are part of this theory-driven, out of the classroom space shared by practitioners, policy makers, and theoreticians. They contrast sacred stories with teachers’ secret lived stories, which tell about real classrooms, and teachers’ cover stories, which portray teachers in a way that is acceptable within the school or the school system.

In this study, NCTM's recommendations are among the sacred stories told to teachers in the last decade. The question is whether these recommendations become part of teachers' stories: cover stories, at least, lived stories desirously. Because this study takes a career perspective, it deals mainly with the stories teachers tell about themselves. Teachers have lived many different stories in their professional progression. This study presents the meaning they make of the stories they lived in many different contexts. Within teachers' organization of their many stories, this reports concentrates on the sacred stories that teachers incorporate to their own, personal professional stories.

### **The Project**

The 5 elementary school teachers involved in this project worked in a K-5 suburban school near a major, southern metropolitan area. During spring 2001, in three individual, open-ended interviews, each teacher worked with a timeline of her career, a logic-spider, and a lifeline. In the first meeting, teachers were presented with a timeline developed from an inventory of professional experiences they had completed. They were asked to comment on different jobs, different schools, and different moments in their careers. In the second conversation, teachers were presented with a "spider" that had knowledge for teaching mathematics as the central theme, and different topics for discussion in the "legs." Teachers choose what they wanted to discuss, jumping from topic to topic. During this meeting teachers also shared lesson plans and mathematics activities they had collected and used in their classrooms. In the last meeting, teachers constructed their own lifeline (Connelly & Clandinin, 1994). They included what they saw as fundamental issues, turning points, and important people in their careers. The different instruments offered teachers opportunities to tell stories from different schools and classrooms, as well as a story of their professional path. All interviews were conducted at the school and most of them took place in the teachers' classroom — during planning time, when students were in other classrooms, or after school hours. They lasted between 45 and 60 minutes. In a final group interview, teachers discussed issues that were repeatedly mentioned in individual interviews. They shared experiences, talked about their school, and discussed what they considered most important in becoming the mathematics teachers they are.

Interviews were audiotaped and transcribed. Teachers received copies of the transcripts of their own individual interviews as well as of the group interview. They were offered the opportunity to comment on the interviews, pointing to modifications or clarifications they would see fit (although they did not make comments). Data were analyzed through constant comparison method using initial descriptive categories such as early teaching, later years, approaches to mathematics instruction, and catalysts for change. Small episodes in the teachers' stories were considered as the unit of analysis, and all information was examined within its context. Although change was part of the initial research interest, it became prominent during the data analysis process because it was such a fundamental part of all teachers' career stories.

Sharon's perspectives were selected for presentation in this report because she began teaching during the Back-to-Basics period and has been teaching through the Standards Movement. Sharon's professional story parallels the story of NCTM's most recent call for changes. Sharon is also currently enrolled in a Specialist Degree program in mathematics education. Therefore, she has been particularly reflective about her mathematics teaching.

### Sharon

Sharon graduated with a Bachelors of Arts in 1975 and got a Master's in Education in 1981. After her first year of teaching, she got married, moved, and did not teach for 2 years. Since the 1978-1979 school year, Sharon has been teaching third grade. She defines herself as a resource person. "My strength is I am a good resource person, I have places to get lots of ideas and I am willing to sit down and work at finding them, if I can find the time to sit down and do that."

In 1988 Sharon began teaching at the school where she now works. She defines her school as a place where teachers have a lot of support. Teachers from the same grade level have common planning time and quarterly plan-it-take-it meetings. They have money to get the resources they need, opportunities to visit other schools that are implementing different ideas, and plenty of chances to participate in professional development activities. All five teachers in the study considered their school as a place of high expectations for students and for teachers. They also considered it a supportive working environment. When asked to make her professional lifeline, Sharon began her line at her current school. "Interesting," she said, "because I probably wouldn't go back longer than being here."

One of Sharon's early mathematics stories is her recollection that she could not memorize her facts in fourth grade. "In our family room there was a coat closet and on either side of the coat closet [my mom] put two nails. And every night we would pull out this chalkboard that hung on those two nails, and we would do multiplication facts till I was crazy." Later, Sharon successfully completed her Algebra and Geometry high school courses. But Trigonometry and Advanced Algebra were a challenge. "I was so lost, I mean, absolutely lost. I had no idea what was going on and I was, you know, in the college prep courses. My friends basically got me through the course and taught me what I learned; which was very little." In college, Sharon took as little mathematics as she could.

When Sharon began teaching, teachers were doing individualized instruction, all very structured. "That was the swing of the pendulum. And everybody had their little folder and you were working on this and that, and everybody was in a different place." Sharon's main teaching resource at that time was her textbook. "When I came in the first time, I had nothing basically to come in and start with, other than the textbook that they handed me."

In 1980 Sharon began her Master's program and later joined a study group. This group discussed different ideas for elementary school teaching.

So then I started doing centers. So that was the last big wave of centers, and then we are back to it again, but, uhm... So I started doing some stuff, but it wasn't as much hands on, but more theme oriented math, I guess. You know, where you tied the math into what you were studying. ... [We did] fun math worksheets even at that time. I mean, it gradually progressed, but you know, at that point in time it was like we would do all things that tied into March, or wind, or lions, you know. So all your math tied into some theme or whatever you were doing in that center. Like there would be a little pattern, or a puzzle at the end that answered the riddle about lions or something. Lions and lambs, it all ended up having some cutesy little puzzle at the end.

In moving from individualized instruction to working more in small groups, Sharon began moving away from the textbook and toward using more "activities." "Very rarely do we just use the book," Sharon says when describing her lessons now. She explains she uses her textbook mainly to organize which lessons she needs to group together. Once she begins to work on a specific unit, she uses the topics of the lessons listed in the textbook to order her teaching. However, for some topics, she uses substitute activities that she considers more meaningful. Sharon does not teach all the lessons that are in the book. Also, during the year, she does not follow the order in which chapters appear in the book. "I move them around," Sharon says.

As an example of activities that she uses, Sharon tells about "racing to one hundred."

My kids have probably played racing to one hundred to learn place value for fifteen, twenty years, you know, where you roll the dice and you add the cubes, and then you do the trading to the tens and you trade until you get to one hundred. We have done that for twenty years, probably, but it still works. ... You know, they understand why you have to do the trading so, if it works, I keep it.

Talking about "keepers" (good activities) Sharon says she doesn't have anything left from when she first started teaching, or from the "cute worksheets" she had.

I kind of dumped off all of the worksheets that were outdated, from when I was in my center, do this worksheet that ties into the month or whatever. So no, I probably don't have stuff that I keep from the very beginning. That racing to one hundred is probably the thing that I have used the longest out of all the games and things that I have used.

Sharon explains that her definition of what constitutes good mathematics teaching has changed over the years. "I used to think that good math teaching was being

able to explain it in a way that the students understood," Sharon says. Although good explanations are still important for Sharon, she now thinks they are not enough. "Different children learn in different ways," Sharon states. So Sharon is aware that some students will not get the ideas she is trying to present just from listening to her. They have to try it for themselves. Sharon particularly notices that children who have a hard time paying attention to her explanations are very good in solving problems and "discovering" mathematics. Also, when children are solving problems or "discovering" mathematics, Sharon has a better idea about whether or not students are on task, understanding what they are doing.

Sometimes you think they are involved when you are doing problems together or, you know, if we are working something on the overhead and talking about why this works and why this doesn't work. But I am basically working the problems and they are just telling me what to do. You think they are involved and they are not. ... So then, with them trying to discover, it is much more obvious if they are not doing anything, that they are not with you, so you can see.

Sharon attributes the initial changes she experienced in her mathematics teaching to colleagues and their collective search for new ideas. "The group of teachers who were teaching third, some of those older people retired, and some other people came in and together we said, this is boring, let's try something different. And it has gradually progressed." Still from that time in the early to mid 1980s, Sharon tells she remembers when her school group became a more social group, and the teachers began to plan together. "So, at some point, like about half way through that 10 or 11 years I was at that school, it changed. It became more of a, what are you teaching, what are you doing, that kind of thing."

Sharon enjoyed the interaction and the collective work with her colleagues—a practice she has cultivated for the past 20 years. Sharing with colleagues and working in a grade-level group is an ongoing theme in Sharon's story. At her current school, she says:

Probably this hall more than any other hall in the school plans together. I mean, everybody knows we plan together. We get together once a week and sit down and do lesson plans and we know what we are teaching, everybody brings what they have. ... In fact, we only turn in 1 set of lesson plan for our hall [grade level].

Some colleagues have particularly influenced Sharon's mathematics teaching. One of the teachers Sharon met at her previous school was particularly important in her development as a mathematics teacher. They were friends at that school and they came together to the school where Sharon is now when it first opened. For 8 years they taught together at third grade in this school, before Sharon's friend moved to another state.

[She] was one of those people, when you came up on something and you just thought, they are not getting this, and I have taught it every way I know how, and you know. Do you have an idea? ... She was into math, that was her thing, what she really loved. Every now and then, when we were teaching something, she would say, now, this would be a good time to use that activity or whatever. She'd remind me to pull something out or just talk about what she had done that day. ... Some of her stuff went too far for me. ... I was more middle-of-the road and she was far out here. But it was far enough that it pulled me that way anyway.

Sharon's friend used to teach mathematics professional development courses and Sharon has taken many of those courses. In general, Sharon values the opportunities she's had to participate in staff development activities. "I guess staff development changed it more than anything," Sharon says. At her school, there are a lot of opportunities to attend these courses.

We have staff development after school. We have staff development during school. We have special staff development days. We do staff development in the summer, I mean. And then you can go away to a staff development course. So, I mean, it is just constant, you know, and every time you go, you bring back a couple of things, you know. You always go and say, oh, I am going to do that, just completely, that was just wonderful. But then you come back and it is not realistic. So you come back and do a couple of things, and that becomes a constant. And the next one you go to, you add a couple more things that turn out to be something that you really keep and that becomes a constant.

Sharon believes staff development opportunities are more accessible now, at her current school, than they were in the past, in previous schools. On the one hand, she attributes these opportunities to the school system in which she teaches. "This is a much more progressive system," Sharon explains, "and we have always had mathematics consultants." On the other hand, Sharon thinks that, in general, there are more resources and opportunities for teachers nowadays. "There is a ton of stuff out there," Sharon says, referring to books, lesson plans on the web, materials one can purchase in teaching stores, and staff development events that show new materials or ideas and how to implement them.

For Sharon, the staff development classes she took provide the connection between her practice and educational research. Sharon claims she does not like to read research. She reads teachers magazines, but for the most part they are practitioners magazines that do not deal directly with research. However, Sharon says the mathematics consultant in her county and the people in charge of offering staff development courses should be in tune with "what is going on out there." Whereas educational researchers

are looking for new ideas on how to better teach, mathematics consultants' job is to translate the new ideas into what relates to classroom teaching. Sharon explains that, as teachers, "we are not necessarily looking at the research. But we are looking at somebody else who has worked at the research." Through this mediated path, Sharon believes educational research reaches her classroom. She tries out the new proposed ideas and if they teach what they are supposed to, Sharon keeps them.

### Discussion

Sharon's story is a story of search. Search for new ideas. Search for resources, for colleagues, for opportunities. Sharon is always looking for what can help her students learn, what can make them understand, what can make her teaching more meaningful to herself and the children in her classroom. As she searches, Sharon incorporates new activities and new approaches to her teaching in general, and to her mathematics teaching in particular. She learns from different sources and uses all she can to implement what she believes is good mathematics teaching. As Sharon looks back at her professional paths, she sees many changes.

Sacred mathematics education stories are incorporated into Sharon's teaching stories. She talks about the swing of the pendulum and about the different educational trends she has lived. As education swings, Sharon learns new ideas, incorporates new suggestions, and develops her teaching. Some of the trends become part of her own search process and she adds those ideas to her own story. In mathematics, Sharon talks about moving from teaching the book, to cute worksheets, to using classroom activities. She mentions having only the textbook as resource to having a plethora of classroom supplies. She says she went from individualized instruction to working more in groups. As her career comes into scrutiny, Sharon organizes it into different times when she used different teaching strategies and resources. Currently, her story incorporates some of NCTM's recommendations for school mathematics such as more hands-on activities and letting students work on problems by themselves to learn mathematics.

Staff development plays an important role in Sharon stories. From her perspective, research results and recommendations for change in mathematics teaching make their way into her classroom mediated by those who offer staff development. Staff development professionals present Sharon with new ideas, which she brings to her classroom. These ideas are incorporated in small doses but, over time, the incremental changes have transformed Sharon's teaching. Sharon sees the past 13 years as especially important in terms of her professional growth and her participation in staff development classes. These 13 years coincide with the release of NCTM's standards. They represent a time of increased calls for teachers to become more professional. They saw a strong push for teachers' ongoing development. Thus, Sharon's stories incorporate and present many of the features that have characterized mathematics teacher education in the past decade or so.

Another important venue for promoting changes in Sharon's teaching over the years has been sharing experiences with her colleagues. Opportunities for professional exchange among peers are part of Sharon's life. She values these opportunities as a way to bring about changes in her classroom. Sharing among colleagues works for Sharon as a continuous professional development environment in which she improves her teaching.

Trying to understand Sharon's teaching by understanding the trajectory of her mathematics practice and examining her teaching from a career perspective, it is quite striking to notice the many changes she perceives in her mathematics teaching. Sharon's career in no way resembles the image of teaching as a job in which changes seldom occur. It also does not present change as a difficult, hard process. Quite the contrary, Sharon's ongoing quest for new ideas, together with changes in working milieu and new educational trends, have led her onto a path of many revisions and alterations of her mathematics teaching practice. Sharon understands change in a way that is in tune with her everyday attempt to improve teaching. From her point of view, change is a natural part of teachers' everyday experiences; it is an obvious and necessary component of good mathematics teaching.

# THE IMPACT OF TEACHERS' CONTENT KNOWLEDGE AND ATTITUDES ON INSTRUCTIONAL BELIEFS AND PRACTICES

Jesse L. M. Wilkins

Virginia Polytechnic Institute & State University

wilkins@vt.edu

This study investigated 407 in-service elementary teachers' level of mathematical content knowledge, attitude toward mathematics, beliefs about effective instruction, use of reform-orientated instruction and modeled the relationship among these variables. Upper elementary teachers (grades 3-5) were found to have greater content knowledge and more positive attitudes toward mathematics than primary teachers (grades K-2). There was no difference in teachers' beliefs about effective instruction, but primary level teachers were found to use reform-oriented instruction more frequently than upper elementary teachers. Overall, it was found that teachers with higher content knowledge were less likely to believe in the effectiveness of reform-oriented instruction and less likely to use such instruction in their classrooms. However, teachers with more positive attitudes towards mathematics were more likely to believe in the effectiveness of reform-oriented instruction and use it in their classroom. Findings from this study have implications for the goals and objectives of elementary mathematics methods courses.

Mathematical content knowledge (Ball, 1990a, 1990b, 1991) and positive attitudes toward mathematics (Quinn, 1997; Richardson, 1996) are both important components of being an effective teacher. Also important are teachers' beliefs about mathematics and mathematics instruction (Grossman, Wilson, & Shulman, 1989) which often impact instructional practices (e.g., Pajares, 1992; Richardson, 1996; Thompson, 1984). In order to better prepare teachers to use instructional practices that follow from the ideals of reform-oriented mathematics teaching and learning (National Council of Teachers of Mathematics [NCTM], 1989, 2000; Simon, 1995) it is important to understand how teachers' content knowledge and attitudes impact their beliefs, and ultimately impact their instructional practices. Thus, the purpose of this study is to: (1) investigate elementary teachers' level of mathematical content knowledge, attitude toward mathematics, beliefs about effective instruction, and use of reform-orientated instruction, and (2) model the relationship among these variables.

In particular, this study investigates the following questions: (1) Does the level of teachers' mathematical content knowledge and attitude toward mathematics differ for primary (K-2) versus upper elementary (3-5) teachers? (2) Do beliefs about effective teaching strategies differ for primary and upper elementary teachers? (3) Does the frequency of usage of reform-oriented instruction differ for primary and upper elementary teachers? (4) Are teacher beliefs about effective teaching strategies related to use of reform-oriented instruction in the classroom? (5) How does the level of teachers'

content knowledge and attitude toward mathematics impact their beliefs about effective instruction and their use of reform-oriented instruction? Information gained from investigating these questions can provide useful information for teacher educators to better develop methods courses that address the many different components of effective teaching.

## Methods

### Sample

This study involved 407 K-5 in-service teachers from two school districts. These teachers were part of a professional development project focusing on the implementation of NCTM-based mathematics curricula.

### Measures

At the beginning of the professional development project teachers' content knowledge, attitudes, beliefs, instructional practices, and other background characteristics were surveyed. Teachers' mathematical content knowledge was measured using a 44-item mathematics test (reliability of test: KR-20 = .88). Items were related to content that would most likely be found in grades K-8. The test was made up of 32 multiple-choice items and 4 open-ended items (multiple-part questions constituting the remaining 12 items). Teachers' attitude toward mathematics was measured using 14 items rated on a 6-point Likert scale (1=*strongly disagree* to 6=*strongly agree*; reliability of the scale based on Cronbach's  $\alpha$  = .88). Teachers were also asked to rate on a 4-point Likert scale (1=*not important* to 4=*very important*) their beliefs about the importance of 14 activity/techniques/strategies for effective mathematics instruction in the grades they teach. Through exploratory factor analysis, a subset of 10 of these items was determined to represent a single factor. Further inspection of the items found them to be consistent with the reform efforts outlined by the NCTM (1989; 2000). These items were used to create a measure of teachers' beliefs about effective instruction (Cronbach's  $\alpha$  = .80). Teachers were also asked to rate the frequency of occurrence of 29 instructional activities in their mathematics lessons on a 5-point Likert scale (1=*never*, 2=*rarely*, 3=*sometimes*, 4=*often*, 5=*all or almost all mathematics lessons*). Again, through exploratory factor analysis, seventeen of these items were determined to form a single factor. Inspection of the items found that they aligned with instructional activities advocated by the NCTM (1989; 2000). These items were used to create a measure of teachers' use of reform-oriented instruction (Cronbach's  $\alpha$  = .87). Measures of background characteristics of teachers were also included such as years of teaching experience (categorized into 7 ranges: 0-2 years; 3-5 years; 6-10 years; 11-15 years; 16-20 years; 21-25 years; 26 or more years), number of mathematics courses taken, and highest degree attained (Bachelor's vs. Graduate).

## Procedures

Teachers were categorized as either primary (grades K-2) or upper elementary (grades 3-5) and compared using descriptive statistics related to their level of content knowledge, attitude toward mathematics, beliefs about effective instruction, and use of reform instruction. Based on the full sample of teachers, a series of path models was used to investigate and compare the relationship between teachers' level of mathematics content knowledge and attitudes toward mathematics and their belief about effective instruction and use of reform-oriented instruction while controlling for number of mathematics courses taken, years experience, and degree level.

## Results

Means and standard deviations of all variables are reported in Table 1 for all 407 teachers as well as by grade level. An investigation of means found that upper elementary teachers have significantly higher levels of mathematical content knowledge and a more positive attitude toward mathematics than primary teachers. There was no difference between primary and upper elementary teachers beliefs' about effective instruction, but primary teachers reported more frequent use of reform-oriented instructional activities than upper elementary teachers. Considering teacher background character-

**Table 1.** Means and Standard Deviations for Variables

|   | All Teachers<br>(N=407) | K-2<br>(N=259)  | 3-5<br>(N=148) |
|---|-------------------------|-----------------|----------------|
| Content Knowledge<br>(KR-20 = .88)  | 27.02 (8.18)            | 25.68 (7.89)*** | 29.37 (8.18)   |
| Attitude<br>( $\alpha=.88$ )  | 4.67 (0.77)             | 4.57 (0.75)**   | 4.83 (0.80)    |
| Effective Instruction<br>( $\alpha=.80$ )   | 3.32 (0.42)             | 3.34 (0.41)     | 3.30 (0.44)    |
| Reform Instruction<br>( $\alpha=.87$ )  | 3.17 (0.53)             | 3.27 (0.52)***  | 2.98 (0.51)    |
| Years Experience  | 3.70 (1.96)             | 3.64 (1.97)     | 3.79 (1.96)    |
| Math Courses  | 3.43 (1.45)             | 3.35 (1.39)     | 3.57 (1.54)    |
| Highest Degree  | 0.39 (0.49)             | 0.35 (0.48)*    | 0.46 (0.50)    |
| Note: * $p<.05$ ; ** $p<.01$ ; *** $p<.001$ ; Asterisks in the K-2 column represent significant differences between K-2 and 3-5 teachers. |                         |                 |                |

istics, a higher percentage of upper elementary teachers reported having a graduate degree than primary teachers. There was no difference in years teaching experience or mathematics courses taken across the two groups.

Intercorrelations between variables are reported in Table 2 for all teachers. Overall, teachers' beliefs in effective instruction was found to have a moderate positive relationship with teachers' reported use of reform-oriented methods ( $r = .42$ ). That is, teachers who believe that reform-oriented instruction is effective tend to use more reform-oriented instructional techniques. However, the magnitude of this relationship suggests that beliefs and actions do not always match.

In order to investigate the relationship between teachers' content knowledge, attitude, instructional beliefs, and instructional practices a series of path models was estimated. Initially, a saturated model, including all possible paths between the variables was estimated. Subsequent inspection of the path coefficients revealed that some effects were negligible suggesting that a more parsimonious model existed. After deleting these paths a final model was estimated. This model, with significant standardized path coefficients, is presented in Figure 1. The chi-square value for the model was not significant suggesting a good fit with the data,  $\chi^2(9, N = 407) = 6.43$ ,  $p = .696$ . Other fit indices further support a good fit of the model with the data. The goodness-of-fit index (GFI) was .996; adjusted goodness-of-fit index (AGFI) = .986; comparative fit index (CFI) = 1.00. These indices can take on a value from 0 to 1 with values closer to 1 showing a better fit and values greater than .90 usually indicating a relatively good fit (Hoyle, 1995). The standardized root mean square residual (SRMR) was .02. This index represents the average residual between the observed and hypothesized correlation matrix. The root mean square error of approximation (RMSEA) was .00. This index takes into account the complexity of the model, that is, the number of

**Table 2.** Intercorrelations Between Variables for All Teachers (N = 407)

|                          | 1    | 2   | 3    | 4    | 5   | 6   | 7  |
|--------------------------|------|-----|------|------|-----|-----|----|
| 1. Content Knowledge     | --   |     |      |      |     |     |    |
| 2. Attitude              | .32  | --  |      |      |     |     |    |
| 3. Effective Instruction | -.11 | .13 | --   |      |     |     |    |
| 4. Reform Instruction    | -.18 | .10 | .42  | --   |     |     |    |
| 5. Years Experience      | -.21 | .05 | .03  | .03  | --  |     |    |
| 6. Math Courses          | .05  | .16 | .02  | .07  | .13 | --  |    |
| 7. Highest Degree        | .24  | .06 | -.06 | -.07 | .11 | .02 | -- |

parameters being estimated. These two indices can range from 0 to 1 with values less than .05 representing good fit (see Byrne, 2001). Theoretically, it is possible for the direction of the path between content knowledge and attitude to be in either direction (see Figure 1). However, based on an inspection of the residual covariance matrix, representing the difference between the estimated and observed covariances, it was decided that the model presented in Figure 1, with knowledge predicting attitude, better fit the data.

Results from the path analysis found a significant negative direct effect of teachers' content knowledge on their beliefs about effective instruction ( $b = -.17, p < .001$ ). However, teachers' attitude toward mathematics was found to have a significant positive direct effect on beliefs about effective instruction ( $b = .19, p < .001$ ). Similar results were found for the occurrence of reform-oriented instruction in the classroom. Teachers' content knowledge was found to have a significant negative direct effect on instructional practices in the classroom ( $b = -.18, p < .001$ ) and teachers' attitude toward mathematics was found to have a positive direct effect on teachers' instructional practices in the classroom ( $b = .10, p < .05$ ). Teachers' content knowledge was found to have a positive direct effect on teachers' attitude toward mathematics ( $b = .34, p < .001$ ). Teachers' beliefs about effective instruction was also found to have a significant positive direct effect on instructional practices ( $b = .39, p < .001$ ).

Indirect effects show a relationship between two variables that is mediated by one or more other variables. For example, there was a significant positive indirect effect of content knowledge on teachers' beliefs that was mediated by teacher attitude ( $b =$

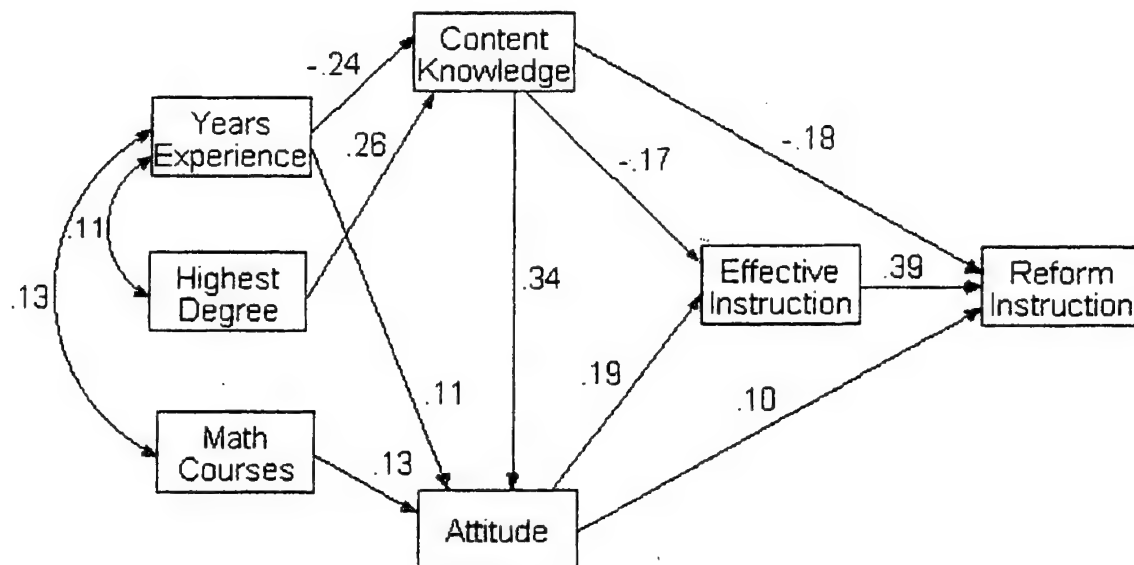

Figure 1. Final path model. All path coefficients are standardized and statistically significant at  $p < .05$ . Fit indices for the model:  $\chi^2(9, N = 407) = 6.43, p = .696$ , GFI=.996, AGFI=.986, CFI=1.00, RMSEA=.00, SRMR=.02.

.06,  $p < .05$ , calculated by multiplying intermediary effects, i.e.,  $.34 \times .19 = .06$ ). This indirect effect is represented by the path that leads from content knowledge through attitude to effective instruction (see Figure 1). However, the total effect of content knowledge on beliefs, found by summing the direct effects and indirect effects, was still negative ( $b = -.11$ ,  $p < .05$ ). There was also a significant indirect effect of attitude on instruction which was mediated by beliefs ( $b = .07$ ,  $p < .01$ ) resulting in an overall greater total effect ( $b = .18$ ,  $p < .01$ ).

Considering teacher background characteristics, there was a significant negative direct effect of years experience on content knowledge ( $b = -.24$ ,  $p < .001$ ) and years experience was found to have a positive direct effect on attitude toward mathematics ( $b = .11$ ,  $p < .05$ ). There was a positive direct effect of degree earned on content knowledge ( $b = .26$ ,  $p < .001$ ). The number of mathematics courses taken was found to have a positive direct effect on attitude toward mathematics ( $b = .13$ ,  $p < .01$ ). Teachers' background characteristics were not found to have any direct effects on either beliefs about effective instruction or instructional practices. However, the impact of these variables was mediated indirectly by both teachers' content knowledge and attitude. For example, mathematics courses taken was found to have a positive indirect effect on both instructional beliefs ( $b = .02$ ,  $p < .01$ ) and practices ( $b = .02$ ,  $p < .01$ ). Years of teaching experience was also found to have a positive indirect effect on both instructional beliefs ( $b = .05$ ,  $p < .01$ ) and practices ( $b = .06$ ,  $p < .01$ ). However, the indirect effect of degree earned was negative for both instructional beliefs ( $b = -.03$ ,  $p < .05$ ) and practices ( $b = -.05$ ,  $p < .01$ ). Because there were no direct effects for these variables the indirect effects represent the total effects.

### Conclusions

Results from this study suggest that primary teachers (K-2) and upper elementary (3-5) teachers differ in their level of mathematical content knowledge and attitude toward mathematics. Upper elementary teachers were found to have higher levels of content knowledge and a more positive attitude toward mathematics than primary-level teachers. However, primary teachers reported using reform-oriented methods of instruction more frequently than upper elementary teachers. Beliefs in the use of effective instruction were not found to differ for primary and upper elementary teachers. Overall, teachers' beliefs in what constitutes effective mathematics instruction was found to be positively related to more frequent use of reform-oriented instruction. However, further investigation of this relationship suggests that teachers' actions do not always align with their beliefs as many teachers who professed the importance of reform-oriented instruction did not report frequent use of such instruction in their classroom (cf. Cooney, 1985).

After controlling for teachers' years experience, mathematics courses taken, and highest degree earned, teachers' content knowledge was found to have a negative relationship with teachers' beliefs and use of reform-oriented instruction. Teachers'

attitude toward mathematics was found to have a positive relationship with teachers' beliefs about effective instruction and ultimate use of reform-oriented instruction. Perhaps teachers who have higher content knowledge feel that since they were successful as a result of traditional instruction that such methods are adequate for their students. In other words, they tend to teach as they were taught. Although teachers' content knowledge is important in helping students to learn and understand mathematics, findings from this study suggest that higher levels of content knowledge alone may not transfer into instructional practices that help promote students' mathematical power beyond basic content knowledge. Teachers who have a more positive attitude toward mathematics may be more able to transfer positive beliefs about mathematics by incorporating what Bishop (1991, 2000) referred to as a mathematically enculturating curriculum that not only promotes students' content knowledge but also instills in them the ideas of mathematics as inquiry-based, as a way of thinking, and as an important part of everyday life. Thus, the importance of teacher education programs goes beyond the development of content knowledge and pedagogical content knowledge to also help teachers develop a positive attitude toward mathematics (e.g., Quinn, 1997) which based on this study may be more likely to transfer into positive instructional beliefs and practices.

The design of this study and the variables used limit the causal links that can be made between the predictor variables and teachers' instructional beliefs and practices. It is quite possible that there are other confounding variables that were not included in this study that may further explain the relationships that were found. For example, perhaps teachers are influenced by the beliefs and policies of their school or school principal. In other words, teachers who are in schools in which reform-oriented instruction is not supported may be less likely to use it even if they believe that it is more effective. Also, consistent with the findings of this study, past research suggests that upper elementary teachers are less willing to use reform-oriented strategies with their students than teachers of students in younger grades (e.g., see Hatfield, 1994 and Gilbert and Bush, 1988, for research on teachers' use of manipulatives). However, this may be due more to the fact that they teach the upper grades than that they have a higher level of content knowledge. In order to take this possibility into account it would be necessary to investigate the relationship between content knowledge and instructional practices across different grades levels. Future models of the relationship between teachers' content knowledge, attitudes toward mathematics and their instructional beliefs and practices would be strengthened by including variables to control for school administrative climate and grade level of teachers. However, even with these limitations, the findings from this study offer interesting insights into the relationship between these variables and provides teacher educators with additional evidence of the importance of enhancing teachers' attitudes toward mathematics as a possible way of encouraging the use of more reform-oriented instruction in the classroom.

### Note

The collection of data for this study was supported by National Science Foundation Grant 9911558. Any conclusions stated here are those of the author and do not necessarily reflect the position of the National Science Foundation.

## COMMUNITIES OF PRACTICE: THE POSSIBILITIES AND LIMITATIONS FOR BEGINNING URBAN MATH TEACHERS

Shea Culpepper  
University of Pennsylvania  
culpeppe@dolphin.upenn.edu

This paper draws on sociocultural theory to explore both the possibilities and limitations of deliberately establishing a community of practice for first year elementary math teachers. The paper describes the findings of a study of one such group of teachers who graduated together from a teacher education program that specifically aimed to prepare teachers for urban settings. The goal in establishing the group was to maintain the learning trajectory begun in a reform oriented math methods course in order to help these teachers resist simply being enculturated into existing practices. The focus of this paper is the ways in which limiting participation to first year teachers influenced the outcomes.

### Introduction

The beginning of the most recent wave of math reform was marked in 1989 by the National Council of Teachers of Mathematics' publication of *Curriculum and Evaluation Standards for School Mathematics*. Inspired by a concern about students' inability to operate in an information society, this document suggested a reevaluation of the way we think about mathematics curriculum. Although it has been more than ten years since these documents calling for reform were published, the norms in most mathematics classrooms remain unchanged. School cultures are powerfully resistant to any kind of reform. Because teachers and their practices are at the heart of establishing these norms, teacher change is critical to achieve reform. Indeed, the persistence of traditional practices in America's classrooms is frequently attributed to many teachers' resistance to change. Accomplishing significant changes places demands on teachers to change the way they think about mathematics, teaching, and learning. Teacher change, however, is not a straightforward process. Teachers do not approach the teaching of mathematics with a clean slate. They are products of the very system they are expected to reform (Ball, 1996). They bring to their teaching previous experiences, both positive and negative. Most importantly, many of these teachers were not taught math in the way reformers are asking them to teach it now. Teachers come armed with their own beliefs in place about mathematics and the teaching of math. These beliefs are often in conflict with those espoused by math reformers, and they are usually difficult to change (Ball, 1990; Ebby, 2000).

### Theoretical Framework

Given this connection between teacher change and the establishment of new classroom norms, approaching the reform of mathematics education for students must

begin with an understanding of how teachers themselves learn about mathematics, teaching, and learning. This study draws on sociocultural theory to begin to develop such an understanding. According to theorists such as Lave and Wenger (1991) learning occurs through increasing participation in the work practices of a group of people who are guided by a shared sense of value and meaning. Newcomers begin participation on the periphery, and over time 'move toward full participation in the sociocultural practices of the community' (p. 29). In the view of the authors, community of practice is defined as a group with shared understandings about what they are doing and why, as well as what it means for the community. Here, learning is both defined as and measured by increasing participation in the community's practices, both in terms of breadth and depth of activity (Lave & Wenger, 1991). The relationship between the community and learning is not a unidirectional one. Lave and Wenger (1991, p. 35) write, "learning is not merely situated in practice – as if it were some independently reifiable process that just happened to be located somewhere; learning is an integral part of the generative social practice in the lived-in world." Thus, the relationship between learning and participation is a dialectical one.

The sociocultural perspective on learning also sheds light on challenges to accomplishing the goals of the mathematics education reform. As communities of practice, schools are likely to prevent changes in practices by enculturating participants, including students, teachers and administrators into traditional ways of thinking about school (Putnam & Borko, 1997). If teachers are to change their thinking and practices, new professional communities of practice need to be created that emphasize active learning, inquiry, and critical reflection. Research on the reproductive nature of school cultures raises a number of questions about how such professional communities can be fostered within or outside of a school. This paper explores whether a community established outside of school settings can interrupt or counter the effects of traditional communities within schools. Stein and Brown (1997, p. 156) claim, "Teacher change is not viewed as happening one teacher at a time, but rather through a process that takes advantage of the synergy, support, and motivation supplied when a "critical mass" of teachers undertakes reform for all students in a given school." Can the same level of synergy and support develop amongst teachers from differing school, even when they do not represent a critical mass of teachers from one school?

### Methods

Data collection for this study focused on the work of an inquiry group for first year teachers. The group met once every three to four weeks, and focused on math related topics of the participants' choosing. This group served as a source for learning about the experiences of first year urban teachers, and the ways in which those experiences were shaped by participation in a community of practice outside of school. The four participants were volunteers who graduated from the same urban-focused certification program in a large northeastern city. Data collection focused on the ways

in which each teacher negotiated conflicts between the various communities in which she participated. Sources of data included the videotaped meetings, individual interviews, classroom observations, reflective journals, and documents that shed light on the norms and practices of the each teacher's school setting.

### **Results and Discussion**

The composition of the group created an interesting learning dynamic. Because the participants were all beginning teachers, the discourse was often focused on sharing mutual frustrations. In spite of the researcher's efforts to maintain an emphasis on learning about math education, the discourse most often evolved into expressions of frustration with working conditions. Advice centered on dealing with parents, bureaucracy, discipline, time management and exhaustion. As one participant said in a mid-year interview, "in some ways it's like the blind leading the blind." However, in an interview at the end of the year this same participant revised her earlier view, indicating that she felt "less threatened" sharing her needs honestly with this group. She suggested that new teachers were less likely to judge her than her experienced colleagues, and that she was more comfortable asking for help.

These findings suggest that the needs of beginning teachers with respect to support in their first year may be very different from the interests of professional developers. While those working towards math reform have a vested interest in seeing new teachers continue to focus on developing their practices in the direction of reform, these teachers may have a greater need for support in simply "surviving" the first year of teaching (Huberman, 1994). In interviews before the school year began, participants indicated that they hoped to get "moral support" from the group. Further, at the conclusion of the study all four cited "support" as the primary benefit of participation. However, in an informal conversation with the participants, each indicated that they had plans to spend a significant amount of time over the summer developing a math curriculum that emphasized what they most valued. The characteristics they mentioned included problem solving, discussion, collaboration, and journaling. This suggests that willingness and an ability to focus on math education may be more present once teachers have overcome some of the other concerns confronting them as novices. This also insinuates that participation in a community that shared the values of math reformers can indeed support teachers in their efforts to resist enculturation into practices that conflict with their own ideals.

The findings also underline the importance of what Lave and Wenger (1991) call "oldtimers." Though the researcher's initial intent was to act only as an observer of the development of this community of beginning teachers, she found herself increasingly called upon throughout the study to offer advice, share resources, and provide insights into the experiences of the participants. While limiting membership to novices had advantages that should not be disregarded, a need did exist for the "wisdom of experience."

## A CALL FOR TEACHER LEARNING GOALS IN PROFESSIONAL DEVELOPMENT

Julie Cwikla

University of Southern Mississippi

julie\_cwikla@yahoo.com

The purpose of this review is to draw lessons from the research on learning environments for students to aid in thinking about learning environments for teachers. The classroom is a learning environment for students just as professional development activities are learning environments for teachers. Research on effective teaching is guided by the learning goals for *students*, and how *these* goals can best be achieved. It follows that research on effective professional development should be guided by the learning goals for *teachers*, and how *these* goals can best be achieved.

The National Council of Teachers of Mathematics (NCTM) has established detailed academic standards to guide K-12 learning goals for students. However, it is unlikely that many K-12 teachers have learned to adjust their teaching with these new learning goals and Standards as the product. Teachers are expected to teach more content in a deep and meaningful manner without sufficient support (Lampert & Ball, 1999). To compound the situation once teachers are in the field, the U.S. education system has no proven mechanism to systematically improve teaching in our classrooms (Stigler & Hiebert, 1999). Research in the area of professional development for mathematics teachers must become more rigorous and attend to the specific features that benefit teachers' development. Yet, the research will not become more systematic until learning goals for teachers and teacher development programs are more clearly defined.

### Theoretical Framework

#### Learning Environments

Students and teachers as learners present different cognitive profiles, but their learning environments are similar in a number of ways. A *deep understanding* of the mathematical content is a goal for both students and teachers as learners. Both learning environments should also be built upon the *prior knowledge* the learner brings to the task or learning situation. *Collaboration* and group tasks have become significant components of students' classroom learning as well as teachers' professional development. Finally, *feedback* and verbal assessment are components of both student and teacher learning environments that might guide the learners' mathematical trajectories toward the learning goals. These similarities suggest that research on student learning and classroom teaching might inform research on teacher learning.

#### Three Studies with Increasingly Specific Learning Goals

It is helpful to review mathematics educational research in the *students'* learning environment. The reviews of the three studies that follow show different levels

of specificity with which classroom learning environments have been investigated. These three studies provide empirically supported guidelines for specific classroom components: (a) the use of classroom time, (b) behaviors of effective teachers, and (c) the order of mathematical task presentation. What is of interest is that the more specific the learning goals of each study and the more specific the components of the learning environment investigated, the more specific the claims that are made about the nature of an effective learning environment (See Table 1).

**Table 1.** Comparison Of Three Studies

| Study                          | Learning Goals                      | Mechanism Studied              |
|--------------------------------|-------------------------------------|--------------------------------|
| Zahn (1966)                    | General - Standardized Assessment   | General - Class Time           |
| Good, Grouws, & Ebmeier (1983) | General - Standardized Assessment   | Specific - Teachers' Behaviors |
| Wearne & Hiebert (1988)        | Specific - Assessment Self-Designed | Specific - Task Presentation   |

Zahn (1966) examined the impact of separating class time into various combinations of "developmental activities" and "practice work" (e.g., 67% developmental, 33% practice) with student learning measured by performance on a three-part posttest. Zahn's data support developmental activities, but the *nature* of the developmental activities that support learning are not revealed and cannot be reconstructed from the data. The Good, Grouws, & Ebmeier (1983) studies looked for relationships between the teacher's use of classroom time and student achievement. Because Good et al. (1983) described the classroom components investigated more explicitly and in more detail than Zahn (1966), they drew more specific conclusions about the features of the classroom practice that affected students' learning. However, because they measured students' learning with a general test, they were not able to make claims about the *nature* of learning influenced by the features. In the final study reviewed, Wearne & Hiebert (1988) designed a program to develop students' conceptual understandings of decimals. Specific assessment tasks were designed to align with the learning goals of the experimental teaching program. Unlike the previously mentioned studies, these researchers designed an assessment closely aligned with the explicit learning goals to evaluate the effects of the experimental mechanism.

Lessons to be learned from these studies follow. (1) When students' *learning goals* are clear and specific, and the feature of the learning environment is described in detail, it is easier for investigators to analyze the specific features of the learning envi-

ronment that contribute to the achievement of the goals. The more specific the learning goals and features investigated, the more specific the research claims about how to achieve the desired learning goals. (2) The *research design* employed to investigate the effectiveness of a learning environment for students or for teachers *must* include explicit goals for the existence of the learning environment. For professional development, how can researchers investigate a program's progress if it is not designed around clear learning goals?

Recently, the field in mathematics education has expanded to include an influx of research on teacher development, teacher change, and professional education. Professional development is a growing area of research in mathematics education yet, the field as a whole remains unfocused. Empirical data have not systematically accumulated, so it is difficult to confirm which features of professional development programs are *most* critical for teachers' ongoing learning. Why does professional development research lag behind its counterpart? One obvious reason is the natural developmental lag between studying students' learning, then teaching, and then learning to teach. However, another reason emerges through examining much of the work on professional development. The literature has not yet provided a set of well-defined learning goals for teachers in professional development in the same way that it has provided learning goals for K-12 students of mathematics.

### **Learning Goals for Teachers**

The spirit of the learning goals for teachers suggested in this paper, parallel the learning goals or NCTM Standards for students, with a focus on depth of understanding rather than discrete behaviors. The literature provides some empirical support and a good deal of conjecture about the characteristics of an effective teacher. Why do these characteristics rarely serve as a basis to develop cognitively based learning goals for teachers?

There are a number of possible explanations why teachers' learning goals have not been made explicit. (1) The current measures of a successful professional program are usually not based directly on teachers' learning (CTGV, 1997). (2) Teaching, for the most part, has remained a hidden profession with teachers working behind closed classroom doors in isolation making it difficult to assess teachers' desired support, their learning needs, and their performance as learners (Shifter & Fosnot, 1993). (3) Professional development has traditionally treated teachers as technicians and not as learners and practical researchers (Richardson & Placier, 2001). (4) The social norms and expectations in a professional learning environment are frequently not supportive of teacher inquiry, learning, and collaboration (Clark & Florio-Ruane, 2001). These issues will probably continue to perpetuate the non-specification of learning goals for teachers until teaching is viewed as a profession that requires continuous learning, careful self and peer evaluation, and perpetual goal setting.

### Summary and Implications

There is widespread agreement in the mathematics education community about the goals for students' learning. There is also agreement about the characteristics of an effective learning environment for students and the characteristics of an effective teacher, but learning goals for teachers remain ambiguous. Until teachers' learning goals are made explicit, empirical research on the methods to support teacher development will not accumulate.

## VOICES OF NEW MATHEMATICS TEACHERS: IMPLICATIONS FOR STAFF DEVELOPMENT

Julie Cwikla

University of Southern Mississippi

julie\_cwikla@yahoo.com

With teacher shortages nationwide it is critical that new motivated teachers are encouraged and supported in their profession. New teachers with less than seven years of experience participating in a middle school mathematics reform initiative were interviewed about their reactions to their professional development support. Overall these teachers were disappointed with interactions in their departments and with their mentors and found support in their interactions with other new teachers across districts. They also expressed a desire for the opportunity to observe their peers.

Huberman (1995) describes new teachers as in a "survival and discovery" phase of their career. As evidenced by teachers' voices reported in this paper, the word "survival" describes not only new teachers' feelings about their teaching and classroom environment but also characterizes their view of professional relationships and support within their school environments.

Middle school mathematics teachers participating in a Local Systemic Change Initiative funded by the National Science Foundation with less than seven years of teaching experience were interviewed to explore the challenges new teachers encounter. This paper focuses on the new teachers' report about their experiences in professional relationships and development activities. The teachers' voices organize this paper into four areas: (1) mentoring, (2) collaboration, (3) content knowledge, and (4) classroom observations. A pseudonym is used for each teacher and all interviews were conducted in 2001.

### Mentoring

All the new teachers interviewed for this study had been assigned a mentor who also taught mathematics. Eileen is in her second year of teaching, just finished undergraduate studies, and is in her early twenties. She reported, "my mentor at my school is, she's older, she's extremely negative. Very hard to talk to. . . (it is) frustrating not to have someone to be able to talk to". Eileen thought barriers in communication might be due to her positive outlook. "I don't know if they think I'm too optimistic. I'm not sure . . . They're so negative. . . I know the kids can do it. I've seen them do it . . . but (my mentor) is just the queen of depression". Mark is also a new mathematics teacher, but has moved to teaching from another career and is in his late thirties. He too communicated a discomfort interacting with his experienced peers. "Conversations are usually dominated by the ones that have been there the longest . . . I thought somebody would ask me my opinion. . . Very many times I felt left out . . . I didn't want (them) to feel like I was questioning the way certain issues or policies were being implemented".

Although Eileen and Mark recalled negative experiences with their mentors and more experienced teachers, they reported benefits from collaborating with other inexperienced teachers, detailed in the next section.

### Collaboration

Two new teachers interviewed for this study met other new teachers at cross-district professional development meetings. They built relationships within their peer group across districts to fill the void of in-school collaboration. Eileen enthusiastically shared the following about her young peer in another district. "We bounce ideas off of each other a lot. . . The fact that she's my own age, she's doing the same thing. We're both new, both new teachers. We have so much in common that I go crazy if we don't talk to each other". Lisa, in her second year also established her own support system. She works closely with a new teacher in a different building. "I talk to her more about what's going on in the classroom than anybody else".

None of the inexperienced teachers interviewed reported positive collaborative experiences in their departments. Patsy recalled,

"we sit around and talk about the (standardized test) scores. Okay, this is what we need to work on. But we never really address how we want to do it. Nothing is ever really hashed out. Your know, it's brought up, and then it's kind of put away . . . I don't think we've ever had a discussion about how to teach a math concept ever . . . it's more like paperwork and numbers".

Eileen added that her department meetings were "more like, housekeeping issues. We need this, we need that". David has been teaching for six years. He spoke specifically about other teachers' attitudes at department meetings. "There are some teachers (that) . . . are just biding their time until they retire. Others are just . . . want to just get it done". Any meaningful conversations about teaching and learning, he noted have been with peers.

The typical teacher isolation that dominates school culture (Ball & Cohen, 1999) does not support new teachers' desire for communication. Lisa forcefully expressed her feelings of isolation and frustration with the other department teachers' apathy and lack of collaboration. "The same way it's got to be told to the undergrads that it's not acceptable for you not to like math, it's got to be said to teachers that it's not acceptable for you to not be willing to talk about what's going on in your classroom". Each of the new teachers interviewed, communicated a need for meaningful collaboration to share ideas about teaching and learning which was not currently supported in their departments.

### Content Knowledge

In addition to their craving for meaningful collaboration, the new teachers interviewed claimed they are equipped with a stronger mathematics content knowledge

than their more experienced peers. During professional development activities when grouped with teachers with weaker content backgrounds those interviewed were disappointed. Eileen shared, "I know I could have gotten a lot more out of it, if it had just been math people, like, just math nerds, ready to talk about math and how to help the kids. There was a lot more time spent . . . catching up the non-math people". Patsy concurred reporting, "We were far ahead of the group, as far as reasoning, figuring out the children's reasoning, I mean, we were sitting there, bored to death".

Most of the new teachers interviewed reported (1) disappointment with the mathematics content reviewed during professional development activities and (2) surprise at their more experienced peers' lack of mathematical understanding. They added that they would have preferred to focus on students' learning, methods of presentation, and the new curriculum rather than the content itself.

### **Classroom Observations**

The new teachers looking for suggestions and ideas from other teachers reported that classroom observations would help them learn about effective teaching methods and might encourage in-school collaboration. Mark suggested that in addition to the administrator observations which he described as only a "snapshot in time," he would like "for somebody to come in who's a peer. You know. 'Oh, I think we do that or we can do this.' Somebody who's not in that pressure cooker". Sally, has been teaching for five years and also shared a desire to observe other teachers. "I'd like there to be some sort of program where we can go and see other people doing what they do. . . I don't even have the opportunity, really, to see other people in my own building, much less at another building. That, I think would be so helpful". David, in his sixth year of teaching suggested that observations by teachers across disciplines might also be helpful. "They'd come into the lesson with the perspective of more on line with the students than of somebody with a math background it might be more in line with what the students might be thinking".

In a separate study (Cwikla, 2002) Joanne, a very experienced teacher, who served as an assistant principal, a principal, and then chose to return to the classroom described the powerful impact of observing other teachers in her capacity as an administrator. "I was not a good math teacher and I learned how to be a good teacher by all the observations. That's what made me better. Was watching so many *successes*. Watching so many *failures*." Joanne had the advantage of serving as an administrator as well as a classroom teacher and supported the voices of the inexperienced teachers interviewed for this study who *all* reported a hope to see other teachers in action and how they operate in their classrooms.

### **Implications**

Staff developers might better support incoming teachers by using these new teachers' views to help structure professional learning environments specifically for

new teachers. One possibility suggested in the teachers' interviews is the development of peer groups of new teachers across schools and districts, providing a caucus for new teachers. Staff developers might also take advantage of these new teachers to aid in helping and teaching those with a weaker content knowledge. Finally observing other teachers through video presentations or classroom visits is an activity this group of new teachers thought might be helpful for improving their teaching. New teachers should be encouraged to practice the research supported reform methods learned at university and feel they are encouraged to perpetuate educational reform.

## A TEACHER-RESEARCHER FOR THE 21<sup>ST</sup> CENTURY

Bronisław Czarnocha,  
Hostos Community College, CUNY, NYC  
broni@mindspring.com

One of the central problems in front of the educational profession is the integration of educational research and teaching practice into a reliable, trustworthy and dynamically developing body of knowledge, which can address successfully the present challenges brought by the requirements of the reform in mathematics education. The urgent calls to address this problem come from several different components of the educational enterprise: a mathematics teacher from NYC, Mark Saul asserts that till now the education research has had very little to offer the classroom teacher flatly (Saul, 1995), while math education researcher Jeppe Scott (2000) observes that the "Present development in mathematics education provide the teacher with little assistance as far as recommendations for teaching methodology is concerned and leaves him/her in an ironic situation of classroom autonomy". Finally Martin Simon, warns that "although constructivism has the potential to inform changes in mathematics teaching, it offers no particular vision as to how mathematics should be taught" (Simon, 1993). The teaching practice/research integration contains two related components:

- (1) from the "pure" research point of view, it involves the change of the site of the research from laboratory to classroom (Brown, 1992).
- (2) from the teacher point of view, it involves the integration of her or his intuitive professional knowledge of teaching with the educational knowledge base in the service of bettering students' learning.

Whereas the first component is being dealt at present by the emerging "Design Research" movement (Collins, 1999; Lesh & Kelly 2002), here we will formulate the basic issues confronting the realization of the second component, the new integrated profile of the teacher-researcher. In fact, King and Lonnquist (1992) inform that action research (teaching research, classroom research) has been unable till now, to make a clear contact between the particularity of classroom research and the general educational knowledge base of the profession. For Noffke (1994), one of the present challenges ahead of Action Research is to clarify precisely if and how, action research can contribute to the traditional knowledge base of the profession. The absence of clear-cut, unambiguous answers to this fundamental question has seriously limited the role of teaching - research as a viable research tool.

In Mathematics Education, this limitation can be now eliminated both conceptually and practically by the introduction of the notion of constructive or cognitive theory of learning into professional discourse. Since the time such theories, which

apply across wide range of studied phenomena (e.g., process-object duality theories (Asiala, 1996; Sfard, 1994; Tall, 2000)), Anderson's cognitive psychology, (Anderson, 1995) or Vygotsky theory (Vygotsky, 1986), appeared in the context of mathematics education, the bridge between the particular classroom situation and educational base knowledge can be much easier established. *As soon as a teacher in the classroom can coordinate her or his teaching-research methodology with one of the theories proven useful and general in the profession, at that moment he or she leaves the particularity of the classroom situation and can view the same classroom as one of the many instances where the particular theory is known to work.* At this moment, the whole conceptual apparatus and methodology of the particular theory can be applied to bear upon the particular classroom teaching-research situation. Thus the general character and trustworthiness of the classroom teaching-research becomes grounded in the generality and trustworthiness of a particular theory of learning with which the classroom situation was coordinated. What's more, the very process of coordination between a theory and practice, one of the modes of reflective abstraction, becomes the central skill required from the teacher-researcher.

The Professional Development of Teacher-Researcher, therefore, must be focused on the acquisition of that skill. Taking into account the essential qualities of Action Research such as improvement of classroom practice in the context of instruction/analysis cycles (King & Lonnquist, 1993), this professional development has to be organized through cyclical methodology around common teaching-research problems and difficulties present in the classrooms. On the other hand, in order to provide a possibility of theory-practice coordination, it has to be a project, a teaching experiment, which is designed on a basis of a general theory of learning (and teaching, possibly), it needs to be designed to provide converging as well as generative results. That means that the research questions of the teaching experiment need to be formulated so as provide an opportunity for both types of results to afford both directions of theory - teaching practice coordination. Finally, in order to provide a sufficiently large sample of students, sufficient number of different classrooms and their teachers need to participate.

Thus the Professional Development of the Teacher-Researcher takes the form of a large-scale cyclical teaching experiment designed on the basis of a general cognitive or constructivist theory to address and to investigate some class of common students' difficulties in the participating classrooms. The goal of such a Professional Development is to transform the participating teachers into highly qualified teacher-researchers, that is individuals

1. whose classrooms are scientific laboratories, the overriding priority of which is to understand students' mathematical development in order to utilize it for the betterment of the particular teaching and learning process;
2. who as teachers can have the full intellectual access to the newest theoretical and practical advances in the educational field, know how to apply, utilize

and assess them in the classroom with the purpose of improving the level of students understanding and mastery of the subject;

3. who as a researchers have a direct view of, and the contact with, the raw material of the process of learning and development in the classroom, act as a researcher in the context of the daily work of and use that process to derive new hypotheses and general theories.

### Conclusions

We see that one simple methodological condition of coordination between research and teaching on the part of classroom teacher fully determines the design and the variables of appropriate large scale teaching experiments. A large-scale experiment in the context of teaching-research methodology means an experiment performed in several different classrooms which serve as different sites of the experiment and the conduct of teaching-research in each conforms to the particularization of the general research questions. It can also be shown that derived here structure of the large scale experiment is a careful composition of the principles of Action Research with the principles of Teaching Experiment of Vygotsky. From Action Research methodology which relies on the individual improvement of classroom teaching by the individual teacher, we employed the cyclic nature of the classroom experimentation and the choice of the focus on the common students' challenges in the participating classrooms. From the Vygotskian Teaching Experiment we took the notion of a large-scale classroom experiment - macro-scheme, according to (Meshchinskaya, 1967), which, in that methodology was performed "to study mental changes under the effect of instruction".

The comparison of the model with other relevant methodologies attempting to bridge the gap between research and teaching practice will be discussed during the presentation together with several examples of such a design.

## THE CHALLENGES IN CONFRONTING TEACHER CHANGE

Mary C. Enderson  
Middle Tennessee State University  
mcenders@mtsu.edu

The purpose of this study was to document factors that influenced a secondary mathematics teacher to teach in a manner supportive of the mathematics reform movement. The research was designed as a case study with the aim to understand one teacher's classroom practices and factors that contributed to her success or failure in implementing reform based practice in classes she taught. Findings illustrate block scheduling was an instrumental factor to her success in creating an inquiry based instructional practice. Questions concerning the influence of the textbook on one's teaching practices were raised.

The *Professional Standards for Teaching Mathematics* (NCTM, 1991) proposes that teachers must be more proficient in: selecting mathematical tasks to engage students' interests and intellect, orchestrating classroom discourse in ways that promote the growth of mathematical ideas, helping students seek connections to previous and developing knowledge, and guiding individual, small group, and whole-class work (p. 1). The *Principles and Standards for School Mathematics* (NCTM, 2000) supports these teacher roles. Although these expectations are sensible, how teachers gain expertise in these areas is not always well defined. Moreover, these visions are in complete contrast to what is common practice among a large amount of the teaching population (Manouchehri & Goodman, 2000). Therefore, the current dilemma in the mathematics teacher education community is conceptualizing ways in which teachers may be motivated to comply with these new ways of teaching. In particular, there is a need to understand how teacher change occurs and factors that might motivate Standards-based instructional practices. This study was designed to address these issues.

### Background and Methodology

Clarke (1997) provided a basis of the framework used to guide this study and is tied to other valuable research in the area of teacher change and practices (Cobb, Wood, & Yackel, 1990; Fennema, Carpenter, & Franke, 1992; Stephens & Romberg, 1985). His framework possessed two key categories for the role of the classroom teacher—what the teacher does and her related beliefs about the teaching and learning of mathematics. Both of these areas were critical in trying to understand the teacher I studied.

The initial study began with a sample of five secondary mathematics teachers, who were students in a graduate-level course where a component of the course was focused on the mathematics reform movement and how teachers viewed the movement "fitting into" their own classroom practices. These teachers taught in four different counties in the Appalachia region of the United States and content ranged from general mathemat-

ics to geometry. After initial interviews and visits to their respective schools, it was concluded that only one teacher had truly embraced mathematics reform teaching in her classroom instruction. This teacher, Ruth, is the case that is presented.

Case studies offer a method of investigating complex areas, composed of numerous parts, necessary in understanding the whole phenomenon being studied (Merriam, 1998). The case of Ruth deals with a teacher in a rural area where the community at large does not believe education beyond high school is necessary. The high school she teaches at has approximately 350 students and operates on a block schedule. Her geometry classes became the focus of this research since she was using a somewhat nontraditional textbook, *Discovering Geometry* (Serra, 1997), as well as nontraditional teaching methods.

Data, collected over a period of one and a half years, included in-depth, open-ended interviews, observations and videotapes of classroom instruction, and written documents such as class handouts, laboratories, homework, and tests. State test scores, used to measure student learning, were also reviewed at the conclusion of the school year. Analysis of data was an ongoing process throughout the course of the study. Data was coded to search for recurring themes, which in turn were used to support or make sense of the factors involved in teacher change.

### Analysis and Findings

Analysis of data was a constant process—searching for patterns with which it could be grouped together. At times there was anywhere from 10-20 themes that were coded and reorganized. These categories were then used to illicit additional information from Ruth either by interview or observation of class instruction. Upon completion of the data collection process, six major categories emerged: knowledge in three specific areas—content, curriculum, and students, making mathematics relevant, confidence level, and comfort level. These themes were presented to Ruth for her review and reaction to determine if there were any additional themes that she believed were lacking from these findings. In one of the final interviews, she indicated an additional factor—her principal's support—being important. While she viewed this as an important factor, it had become a component of her "comfort level" grouping rather than a "stand-alone."

Using Clarke's work (1997) as a framework for this research was valuable in that the findings were in two specific areas—"what the teacher does" (her actions) and "beliefs about teaching and learning." Both areas were at the forefront in trying to make sense of what influenced Ruth's practices to change and what factors influenced her to teach in a reform-based manner. Her actions provided evidence that she was willing to take risks in providing her students with nontraditional types of experiences and that she also was willing to put in the time it took to accomplish this. She wanted the mathematics to be relevant for her students – whether they would work in factories, the logging business or teach school – and was willing to take whatever measures

were necessary to do this. She also believed that she would not have changed her practices if she had not had the opportunity to collaborate with other teachers in her graduate work. Since she was in such a small school district, her professional development came out of her graduate studies. She had been a traditional teacher—lecture and lots of examples—but came to realize that not all students would learn the mathematics in this way and she wanted them all to be successful.

### Discussion and Conclusions

Although the reform movement's perspectives on teaching and learning encouraged Ruth, she was not always clear about how to make change occur on a regular basis. She expressed concern that "I might not be able to do the things I do with my students if the school wasn't on block." She had a difficult time finding literature that would help her in her transition and she voiced this on a number of occasions. While there exists research in teacher change, much of it relates to elementary and middle levels. By and large, high school teachers still have not "bought into" the reform movement practices. Thus, it is important that further research be conducted in this area.

Questions related to the textbook used for classroom instruction were also raised. Ruth believed the textbook helped her think about geometry differently than how she had learned it and it gave her some flexibility in organizing inquiry-based activities for her classes. This raises the recurring question on how textbooks drive what occurs in the classroom.

Another area that needs additional attention is how teacher change occurs in rural schools. Ruth is one of many teachers who are in isolated areas with little to no support for teacher development. A large part of this is due to funding—or lack of funding. Since the populations served are smaller in number, a large percentage of education dollars must be spent on updating or renovating schools. Little money is available for the professional development of teachers, updating laboratories, and purchasing technology equipment. Thus, the research community cannot overlook the difficulties teachers in rural schools must struggle with in order to make change happen.

If we, as a mathematics education community, expect for teachers to change their practices, then we need to be leaders of reform in teacher education programs. This is especially important in mathematics content courses pre- and inservice teachers take in their programs. We must continue to make progress in defining what mathematics reform looks like and how one gets there. Future research must provide society at large with such evidence.

## **INTERMATH: TECHNOLOGY-ENHANCED, LEARNER-CENTERED PROFESSIONAL DEVELOPMENT<sup>1</sup>**

Ayhan Kursat Erbas, Shannon Umberger, Evan Glazer, & Chandra Hawley Orrill  
University of Georgia  
intermath@coe.uga.edu

In this oral presentation, we discuss findings from the implementation of InterMath (<http://www.intermath-uga.gatech.edu>), an NSF-funded, web-based initiative geared toward improving mathematics teaching and learning in the middle grades. We examine two workshops to determine what goals were and were not met by participants in this professional development environment. Furthermore, we focus on the experiences of the learners, offer insights from across both cases, and provide suggestions to improve the experience for later learners.

InterMath has been developed based on the recommendations of leaders in professional development and mathematics who have clearly defined a working plan for improving mathematics teachers' content knowledge and pedagogical content knowledge—two factors critical to student learning. InterMath responds to calls for professional development that occurred over an extended period of time, emphasizes teacher thinking and development of reflective dispositions, and pushes teachers to learn more in their content areas (e.g., Ball, 1994; Hawley & Valli, 1999; Krajcik, Blumenfeld, Marx, & Soloway, 1994). As one facet of a larger effort, InterMath addresses the vision of teacher learning laid out by Kilpatrick, Swafford, and Findell (2001): "Teachers' professional development should be high quality, sustained, and systematically designed and deployed to help all students develop mathematical proficiency" (p. 12). This statement is a call for professional development experiences that depart from the "make and take" model that has pervaded teacher professional development. InterMath provides one format for meeting the growing need for constructivist, learner-centered environments (Hawley & Valli, 1999; McCombs & Whisler, 1997; National Staff Development Council [NSDC], 2001).

The InterMath experience includes a 15-week technology-rich workshop, a website with mathematical investigations and tools to support learning, and an ongoing support system designed to provide continued support for previous participants. The InterMath workshop itself supports its participants in developing content knowledge and technology integration by allowing the participants to use a variety of technological tools (e.g., Geometer's Sketchpad, Excel, and NuCalc) to explore open-ended investigations. In implementation, InterMath allows participants to choose their own paths—they select which problem(s) they want to work; the approach they want to use to solve the problem; and ultimately, the depth of their learning experience.

For this study, we collected data in two InterMath workshops. The larger of the two workshops included approximately 26-28 participants (this number varied due to

attrition and late enrollment). These participants were full-time middle school teachers enrolled in a district-sponsored graduate degree program in mathematics education. The workshop served as their introductory course for a three-year degree program (separate from the InterMath workshop). The workshop instructor was a mathematics education professor and one of the InterMath developers. Two graduate assistants served as participant observers during the workshop, and the project manager visited the class three times during the semester to act as an outside observer and to conduct interviews with participants.

The second workshop was held at the University of Georgia (UGA). The class began with seven participants from nearby middle and high schools; however, only four completed the workshop. Two of these participants taught eighth grade mathematics at a rural middle school. The other two participants came from a private school—one was a sixth grade mathematics teacher; the other was the school's technology support person who also had a mathematics education background. A professor from the mathematics department at UGA led the workshop. There were three graduate assistants who were responsible for supporting the teachers and taking field notes. Again, the project manager conducted interviews with this group.

The classes both met once per week for three hours. During the first portion of each class, the instructor demonstrated explorations and answered participant questions. The participants then shifted to the computers to work on investigations and write-ups of investigations for the remainder of the class. For their final product, participants were expected to complete a web-based portfolio comprised of their write-ups.

The data considered for this report include observations from three meetings of each class (an early, a middle, and an end session), interviews with some of the participants, and the online materials produced by those participants. We included tape-recorded interviews with eight participants in the first workshop, all four participants in the second workshop, and both instructors. There were also informal interviews conducted half-way through the course in the first workshop. Participant portfolios of the people interviewed were also analyzed.

Observation and interview data were analyzed using coding techniques (similar to those described by Merriam, 1988) to identify key themes. Each subset of data was analyzed by at least two people on our research team. Once the themes were identified and agreed upon by both researchers, cross-case analysis was used to determine which themes were characteristic of both workshops. The findings and recommendations are based on those emergent ideas that crossed the cases.

Participant portfolios were analyzed by two researchers for each class. The analysis consisted of using a rubric that considered the quality of mathematical thinking and the demonstrated technology use. By using this approach, we were able to watch for changes over time and for trends among learners both within and between the two workshops. Our findings show that support and interaction became intertwined. We

noted that there were two kinds of interactions: affective (aimed at providing positive feedback or other motivation) and intellectual (those that provided the information learners needed in order to make progress on their investigations).

There were two main barriers across the two cases: technology and goals. Participants' inexperience with the software and hardware significantly impacted their learning experiences. Moreover, the participants' goals and the workshop designers' goals were not always in alignment, leading the two groups to focus on different aspects of the learning experience.

Another major finding in the cross-case analysis was disturbing. There was a trend among some participants to implement the InterMath problems into their classrooms by structuring their students' learning experiences exactly as their workshop experience had been structured. In short, it seemed that the participants borrowed InterMath rather than adopted it. It may be argued that this is the first step of adoption; however, it was problematic because middle school students are not necessarily ready to have a learning environment quite as open as the InterMath workshop had been. Perhaps worse than directly implementing InterMath, however, was the overwhelming number of participants who were afraid to provide their students with any learner-centered instruction. This fear led them to avoid implementing any InterMath ideas at all.

In conclusion, we have developed suggestions for the improvement of the InterMath workshop experience. First, it is vital to the success of the workshop that we simplify the technology for developing the online portfolio because when the participants were struggling with technology, they did not engage in content knowledge development. Further, we learned that simply telling the participants about the intentions of the workshop was not enough. The structuring of the workshop needs to challenge the participants to push themselves. The participants need to have the opportunity to develop their own goals in order to establish individual ownership of the workshop itself. Finally, participants need to feel that they can work with the instructor(s) to steer this professional development program in the direction that maximizes their success.

From our experience in these two workshops, it seems reasonable that a first step toward more meaningful adoption by the participants would be to attack the problem head on: to discuss ways to implement InterMath with the participants, to look at ways the investigations might be modified to more appropriately meet the needs of middle school students, and to discuss the value and learning that might come from using the investigations. A second step might be to actually model a classroom approach to using the investigations with middle school students.

### CRITICAL EXPERIENCES FOR ELEMENTARY MATHEMATICS TEACHERS

George Gadanidis

bonilyn@hotmail.com

We define as critical those experiences of epiphany that cause teachers to reflect on their knowledge and beliefs and see mathematics and mathematics teaching in a new light. When such moments of epiphany occur mathematics education artifacts – such as curriculum documents, classroom experiences, ideas from professional development workshops, journal articles, and so forth – can be thought of as inkblots where the image appears to shift and something new is seen, something that was not apparent before. As one teacher in our study commented, “I feel like [this experience] has cleaned my spectacles.” Similar findings are reported by McGowen and Davis (2001) where one teacher noted that course experiences “opened [her] eyes to a new outlook on mathematics” (p. 444).

Some research indicates that for significant change to occur in teachers’ beliefs and practice, teachers need the opportunity to engage in practical inquiry and reflection about mathematics and mathematics teaching (Borko, Mayfield, Marion, Flexer and Cumbo, 1997; McGowen & Davis, 2001; Stipek, Givvin, Salmon and MacGyvers, 2001). One of the “practical inquiry” experiences of the 20 teachers in our study was to mentally solve arithmetic problems such as  $16 \times 24$  and  $156 + 78 + 9$ . In an asynchronous discussion forum, teachers shared the mental solution methods they used, and they reflected on the pedagogical implications in light of two articles they read on children inventing personal algorithms for arithmetic operations (Burns, 1994; Kamii, Lewis & Livingston, 1993). Teachers also shared their personal views and stories of mathematics. Transcripts of online discussions were analyzed using a comparative case study approach to determine common and disparate characteristics of teachers’ perceptions of mathematics and mathematics teaching.

In the beginning of the online course, teachers shared their views of mathematics by telling stories of personal experiences, which we categorized into three types of stories about mathematics. One type of story involved an aesthetic connection to childhood and family – a view of mathematics that is both social and playful. This was manifested in statements, such as “I LOVE math. I always have. I, like many of you, had many problem-solving car trips. I still get excited when I see a license plate that I can make ten with (using any means).” Note the aesthetic nature of the teacher’s statement – the verbal expression of delight and the use of capital letters to convey her emphasis. Also note the aesthetic qualities of the open-ended mathematical problem

of “making ten” using “any means” which contrasts sharply with the more traditional approach that insists that one finds *the answer*, to, say,  $5 + 5$ . The person “making ten” has the opportunity to use her imagination and to find personal, creative ways of looking at mathematically combined digits on license plates. Sinclair (2001) suggests that aesthetically rich mathematical experiences enable us to “wonder, to notice, to imagine alternatives, to appreciate contingencies and to experience pleasure and pride” (p. 26).

A second type of personal story of mathematics was characterized by a persistent negative aesthetic connection to traditional school experiences and feelings of incompetence and failure: “I grew up with very negative feelings towards math. I felt that there was a time pressure to answer quickly and I panicked when confronted with this. I feared the thought of failure or looking stupid when others could answer so quickly.” In contrast to positive stories about mathematics that were in part family-based, the negative stories shared by teachers were school-based. This is not to say that all home experiences of math are positive and school experiences are negative, rather, that in our study mathematical activity in the home was remembered fondly and its pleasurable affects continued to be felt in adult life. A third type of personal mathematics story that emerged was characterized by a passive attitude towards the subject. There wasn’t a feeling of failure but neither was there a feeling of excitement or enthusiasm. One teacher commented, “I did not hate math in school but I didn’t love it either. I went through the motions.” In our study we noted that teachers across these three groups appeared to have been positively affected by the critical experiences offered in the online course. Teachers in the last two groups expressed optimism about a renewed interest in mathematics.

We suggest that the experience of mentally solving  $16 \times 24$  or  $156 + 78 + 9$  is aesthetically rich in that the mental processes involved do not demand rule-based procedures. How people solve  $16 \times 24$  depends greatly on how they personally interpret the problem. For example, some people may multiply 16 and 25 and then subtract the extra 16. Others may deconstruct the problem as  $10 \times 24 + 6 \times 24$ . Many other solutions processes are possible – even ones that use algebraic structures like  $(20 - 4)(20 + 4)$ . Given such problems, people are eager to share their solutions, they express interest and sometimes surprise in the solutions of others, and are motivated to try to come up with different solution processes. Open-ended inquiry, interest, surprise, and motivation are characteristics of an aesthetic approach.

Teachers noticed that their mental solution processes for  $16 \times 24$  or  $156 + 78 + 9$  differed from the standard algorithms for addition and multiplication, and that several different solution processes emerged: “When I added  $156 + 78 + 9$  I started with  $156 + 9 = 165$ . Then I added  $165 + 80 = 245 - 2 = 243$ . This is different than when I did it with paper and pencil because I [...] solved my problem by starting with the bigger numbers first (left to right, not right to left!).” Such experiences appear to have helped

teachers develop a deeper understanding of what constitutes mathematical activity and mathematical understanding in the context of addition and multiplication. "To me, the implications are that doing arithmetic mentally requires real understanding. The traditional way (on paper, doing the "ones" first) is more of a procedure to be memorized that requires little understanding." As was the case in the study by McGowen & Davis (2001), teachers in our study made important connections between their experiences and ideas in the articles they read. "I do agree with Kamii and Burns' points of view. [...] I think that by having the student discover a successful method they will be more likely to internalize and understand the concept. In coming up with their own methods they are doing the thinking the way their mind works. We can see [in our discussion] that everyone processes things differently." The combined experiences of doing mathematics and reading the scholarly papers on children inventing algorithms resulted in some change in how teachers interpreted curriculum documents.

After seeing how different people calculate, I better understand this last overall expectation in [the curriculum document]. Hmph! It is not until I do something myself, do I more fully understand the language and what the curriculum is really driving at. Thus students need to explore different ways of doing calculations, talking about it, communicating their ideas in a variety of ways. [...] I am reading the document with new vision.

### Discussion

Contrary to the usual alignment of "critical" with "rigorously intellectual," participants in our study revealed that critical engagement occurs within an aesthetic context. This was true for teachers with diverse mathematical backgrounds and attitudes that ranged between positive and negative. The interplay among the mathematical experiences, journal readings, and online reflections and discussions created a critical tension that helped teachers understand mathematics and mathematics teaching in a new light. The experience of struggling to solve simple arithmetic problems mentally helped teachers realize that these problems may be solved in many different ways. The journal articles placed their experiences in the broader context of mathematics pedagogy. The opportunity to share, compare, and discuss ideas online also benefited the teachers. No one experience can create comprehensive or permanent changes in teachers' perceptions of mathematics and mathematics teaching. Neither does one experience significantly affect teachers' classroom practice; teaching is also greatly affected by accepted teaching practices in the wider school community (Buzeika, 1999; Ensor, 1998) and by conflicting priorities (Skott, 1999). However, critical experiences are important starting points for change in teachers' perceptions and classroom practice.

## THE STRUGGLES OF A COMMUNITY OF MATHEMATICS TEACHERS: DEVELOPING A COMMUNITY OF PRACTICE

Cristina Gómez  
The University of Alabama  
cgomez@bama.ua.edu

The purpose of this study was to understand how participants in a professional development program initiated, developed, and supported a learning community focused on students' understanding. The analysis focuses on teachers' activity as they participated in a community of practice and how that participation promoted (or restricted) their learning and therefore their students' learning. The components that characterize a community of practice are 1) mutual engagement, 2) a joint enterprise, and 3) a shared repertoire. The study took place in a bilingual (English-Spanish) high school in a large district in the Midwest, with a high percentage of Latino/a students, and situated in an urban setting. The study shows how the community was transformed by the practices and resources available to the members.

### Introduction

Mathematics teachers' participation in communities of practice has been identified as a promising strategy for professional development. Studies focused on school organization have found strong relationships among teachers' participation in professional communities, innovative practices, and student learning (Lee, Smith, & Croninger, 1997; Louis, Marks & Kruse, 1996). Mathematics teachers who participate in communities of practice are more willing to change their practices and their learning becomes generative (Franke, Carpenter, Levi, & Fennema, 1998). While studies have found that teacher' participation in communities of practice is one significant element for supporting teacher change, we do not know how those communities are constructed and supported. In many studies, the communities were already organized or, in some cases, the communities emerged from the reform process in ways that are not clear. Regardless, communities are important in supporting both mathematics teachers' and their students' learning.

The purpose of the present study was to understand how participants in a professional development program initiate, develop, and support a learning community focused on students' understanding. The analysis focuses on teachers' activities as they participate in a community of practice (Wenger, 1998) and how that participation promotes (or restricts) their learning and therefore their students' learning. The three dimensions characterizing a community of practice are 1) mutual engagement, 2) negotiation of a joint enterprise, and 3) development of a shared repertoire. This study seeks to describe how a specific design for professional development serves the different requirements for learning defined on a framework in which communities of practice and participation in those communities are the fundamental unit of analysis.

Such a conceptual framework emphasizes the negotiation of meaning and the building of identities, which take place during the development of practice (Wenger, 1998).

### Methodology

This study focused on the community formed by teachers and researchers. There were two opportunities in which researchers and teachers were engaged in common activities. One was the general meetings and the other was the conversations after class—reflection meetings. The data correspond to two year's texts produced through transcripts of teacher-researcher conversations during the general meetings and the reflection meetings. The analysis began reading through all data as a complete corpus to get a sense of what happened over time. Codes for analyzing participant characteristics were used in this first stage. The result of this first reading was the description of the history of the community and the identification of themes that were later used on the second stage to fracture the data.

The second stage, explanation, was focused on the three questions related with the mechanisms for community formation: a) What are the possibilities for mutual engagement? b) How is alignment secured? and c) What material supports imagination? To answer these three questions, the coding system was organized to reflect characteristics of the community. Based on the framework, three aspects were defined as fundamental to support the formation and development of the community and to provide facilities for each one of the components.

### Change and Development

Every community of practice evolves in its own way. Looking at the facilities for engagement, alignment, and imagination available each year it is possible to see how they changed. There are at least four aspects that deserve attention—the structure of the meetings, the content of the meetings, the discourse of the community, and the forms of engagement. During the first year, there was no clear structure for the meetings. While the researchers wanted to be open to teachers' suggestions, teachers' concerns directed most of the meetings. The amount of time spent in discussing scheduling for following meetings was very large during the first year but it was not an issue during the second year. From the very beginning of the second year, the meetings frequency was set and most scheduling conflicts were discussed during the reflection meetings or via e-mail.

During the first year, the teachers were in charge of setting the agenda for some of the meetings and the researchers were often uninformed about the topics or questions that would be addressed that day. On other occasions, the researchers had prepared some activities for the teachers and during the meeting the lack of preparation or other teacher's concerns changed the way the meeting was run. In contrast, during the second year, the researchers prepared all the meetings, having goals they expected to meet and discussing with the teachers in advanced the activities they would like to be involved.

The second difference deals with the content of the general meetings. Looking at the facilities for engagement, especially the aspects related with continuity, there is a clear difference in the relation among the topics covered during the meetings. During the first year, each meeting could be described as 'addressing one topic'; during the second year the continuity of activities and contents across meetings was more evident.

These differences in activities and content were translated to differences in discourse of the community, the third difference. During the first year, most concerns were related to issues external to the community—school restrictions, proficiency exam, and curriculum. During the second year, the conversations were directly related with teacher's practice. Even though, during the first year, the teachers shared stories from their classrooms and the community had conversations about specific mathematical content areas, such as algebra; it was only during the second year that the group discussed specific examples of students' thinking, criteria for selecting worthwhile tasks, and the role of the teacher in classrooms that promote understanding.

Finally, the forms of engagement changed drastically from one year to the next. During the first year, all the teachers participated in the discussions during the meetings, some more involved than others, but the attempts to make changes in practice took place outside of those discussions. During the second year, there was a conscious and deliberate attempt to involve the teachers in making changes in their practice. It was not forced, of course, but it was the ultimate goal. All the activities were directed to give teachers tools to understand student thinking, to have clear goals, to select appropriate tasks, and to take new roles in the classroom. And because of these intentional actions, the teachers had more opportunities to participate in meaningful activities, to work with others, to produce artifacts, and to be really engaged in the process of community building.

### **Implications**

The study contributes to research in professional development in two ways, (1) understanding how a community of practice emerges and (2) validating the relevance of the content on professional development programs. The framework used helped to describe the different stages of the community and the way the group matured over time. Looking at the facilities available for each component during the process of community formation has given a detail description of what activities the participants were engaged in, what goals they negotiated, and what tools they produced during these activities for reaching the goals. The description brings to the front the importance of the content in the development of the community.

The second contribution to the research literature is the relevance of the content in professional development programs. The changes observed from the first year to the second year, show how important is the content of the conversation in a professional development program. Only when student understanding was the real focus of conver-

sations and the community had tools to talk about it, did the teachers engage in more meaningful activities. The focus of the discussion was always highly related with the mathematical content, specifically with student development of algebraic reasoning.

## **INTERWEAVING AN ONGOING PROFESSIONAL DEVELOPMENT PROGRAM WITH EVERYDAY CLASSROOMS**

Hea-Jin Lee

The Ohio State University, Lima

lee.1129@osu.edu

This report is based on a professional development program project funded by the state of Ohio and the Regional Professional Development Center. The program was designed to provide middle school mathematics teachers with both content and pedagogical content knowledge. Eight graduate credits were offered from January 2001 through December 2001, and a total of twenty-five middle school mathematics teachers in grades 5-8 participated. Overall, it was observed that the project was conducted in a manner consistent with the proposed goals, objectives and stated outcomes.

### **Research Questions**

The purpose of this study was to find strategies for enhancing professional learning, as well as developing effective professional development models. The focused research questions were (1) What are teachers' expectations from the professional development program? (2) How do experienced teachers adopt/adapt new content/pedagogical knowledge in their classroom?, and (3) What are effective systematic aids to support teachers' professional development, including their content and/or pedagogical knowledge?

### **Theoretical Frameworks**

Professional development is a critical ingredient of mathematics education reform. Effective professional development experiences are designed to help teachers build new understandings of teaching and learning via the trying out of strategies that help students learn in new ways. Loucks-Horsley, Hewson, Love, & Stiles (1998, p. 36) listed the principles that are addressed in effective professional development experiences: such experiences are driven by a well-defined image of effective classroom learning and teaching; provide opportunities for teachers to build their knowledge and skills; use or model with teachers the strategies teachers will use with their students; build a learning community; support teachers to serve in leadership roles; provide links to other parts of the education system; and are continuously assessing themselves and making improvement to ensure a positive impact on teacher effectiveness, student learning, leadership, and the school community.

Jones, Swafford, and Thornton (1992) discussed the major concerns that evolve around the need for professional development programs. For example, programs should actively promote "individually guided" teacher activities; generate conditions for significant follow-through and feedback on new teaching practices; provide opportunities for teacher input and involvement in establishing and developing the

professional development program; support an inquiry approach for addressing teachers' pedagogical problems; and generate a knowledge base for effective teacher decision-making. Nowadays, these concerns are still critical to the success of programs. In addition, more issues to be considered for the success of professional development programs are ensuring equity, building professional culture, developing leadership, building capacity for professional learning, generating public support, supporting the effective use of standards and frameworks through professional development, finding time for professional development, and evaluating professional development.

Professional development does not occur as an isolated strategy. Every program uses a variety of strategies in combination with others. According to the National Staff Development Council (Sparks & Loucks-Horsey, 1990), five different models of effective staff development for teachers were: training, individually-guided staff development, observation/assessment, involvement in development/improvement process, and inquiry. These can be used singularly or in combination (Brown & Smith, 1997). These strategies covered the professional development models adopted by several different institutions or organizations, as well as by this project.

### Research Methods

This study was conducted from January through December 2001, during which an introductory workshop in the winter quarter and three consecutive workshops (spring, summer, and autumn quarters) were provided. Twenty-five (6 male and 19 female) middle school mathematics teachers in grades 5-8 participated and earned 8 graduate credit hours. The participants experienced four workshop sessions throughout the year, including theoretical trends in mathematics education, hands-on activities, analyses of student work, using technology, the use of curriculum materials, understanding NCTM Standards and the Ohio model, collaborative work, issues related to assessment, and discussions followed by activities. Reflections on practice such as reflections on audio and video taped self-taught lessons were required. WebCT (Web-based communication tool) was used to communicate among teachers and instructors. Poster presentations and presentations in a mini-conference were conducted to share what they learned with other teachers. In addition to the in-class program, project instructors and a consultant visited participants' classrooms. These site visits provided a better understanding of the participants' needs, as well as the project impact on teachers' content knowledge and pedagogical techniques.

The main data sources of the study were observations, interviews, and written documents such as concept maps, journal entries, teacher reflections on practices, and pre- and post-project survey questionnaires, and commentary notes from site visits by the project consultant.

### Findings

(1) What are teachers' expectations from a professional development program?

Overall, participants' expectations from the professional development program were to learn: new ways to effectively teach math; how to get my students more actively involved in learning mathematics; and strategies to show students why things work. They were more interested in actual practices that can be taken to the classroom rather than theories. Teachers were also eager to make new professional connections through the program.

(2) How do experienced teachers adopt/adapt new content/pedagogical knowledge in their classroom?

Teachers' reflections in their journals show what activities/contents influence their learning to teach, as well as what factors act as incentives/hindrances to enriching their professional development. Teachers appreciated visual representations, links to literature, cooperative learning, hands-on and fully engaged learning, talking about things, understanding "Why," opportunities to brainstorm with other teachers, alternatives to traditional texts, connecting to the way children think, and so on.

(3) What are effective systematic aids to support teachers' professional development, including their content and/or pedagogical knowledge?

Each activity of the workshops was developed to accomplish the project goals and anticipated outcomes. The following are few of systematic aids used for the workshops: encouraging teachers to learn mathematics in an active participatory manner; solving problems and justifying their solutions to enhance mathematics content knowledge; using technology; using videotapes to improve instructional practices; clarifying beliefs about teaching and learning mathematics; assessing student understanding of mathematics concepts and procedures; monitoring student performance in mathematics tests; conducting inservice workshops/seminars for mathematics teachers; and so on.

### Discussions

The paradigm shift in professional development suggests a change in emphasis from transmission of knowledge to experimental learning; from reliance on existing research findings to examining one's own teaching practice; from individual-focused to collaborative learning; and from mimicking best practice to problem-focused learning (Loucks-Horsley, 1995; Sparks, 1994). What teacher educators and teachers should keep in mind to enrich professional development programs are that professional learning must be relevant to student learning. Also teachers should stop receiving one-shot workshops and become active decision makers in the process of designing and choosing professional development opportunities. Professional devel-

opment initiatives in mathematics should have an appropriate level of challenge and support, provide activities demonstrating new ways to teach, use a team approach, provide time for reflection, and evaluate the effectiveness and impact of the activities. In addition; follow-up to the professional development program should be provided – such as opportunities for practice in the classroom; the professional development program designer's challenge is to assemble a combination of learning activities that best meet the specific goals and context. In summary, professional development should be viewed as a critical component of reform. The goals of a professional development program must be linked to the goals of students' learning and assessment, preservice teacher education, and school leadership.

## **CURRICULUM MATTERS: THE IMPACT OF A PROFESSIONAL DEVELOPMENT PROJECT ON TEACHERS' UNDERSTANDING OF CURRICULUM AND CONTENT**

Jean J. McGehee

University of Central Arkansas  
jeanm@mail.uca.edu

Linda K. Griffith

University of Central Arkansas  
lindag@mail.uca.edu

If we want teachers to apply research to their practice, then we should demonstrate how the application impacts the very issues that concern them daily in the classroom. Currently Standards-based curricula and teaching held accountable by state testing programs are at the center of education concerns and reform. Gandel & Vranek (2001) report, "When they are well devised and implemented, academic standards and tests, and the accountability provisions tied to them, can change the nature of teaching and learning. They can lead to a richer, more challenging curriculum . . . When they are poorly devised and implemented, [they] can become a distraction and a source of frustration in schools." They also conclude that standards matched by equally rich and rigorous tests that become more challenging at each successive benchmarking grade and intensive professional development make a difference between high and low quality programs.

Since January 2000, the Professional Development and Curriculum Alignment Project (PDCA) has used the state criterion-referenced test as an opportunity for research and reform in teacher knowledge and practice. The project, which involves teachers in grades 3-8 at Site 1 and grades K-8 at Site 2, investigates the effectiveness of a professional development model based on coaching (Joyce & Showers, 1988; Weathersby & Harkreader, 2000) and alignment of the intended (written), the taught, and the tested curricula (Glatthorn, 1999; Hayes Jacobs, 1997).

Motivated by a concern over low state test scores, administrators from each site initiated the contact with university mathematics educators. The criterion-referenced tests benchmark student achievement at grades 4, 6, and 8. These tests are rich in that they assess computation in problem contexts and heavily weigh open response items in the raw score. The two sites were not looking for quick fixes. Teaching to test items and adopting a "test-guaranteed" textbook program would inadequately address their problems. However, the university educators proposed that the released test items could be used to help teachers begin to understand the complexities of curriculum and to wean them away from textbook reliance.

PDCA has two components, summer institutes and site visits. The goals of the summer institute are to:

- To develop teacher knowledge by focusing on a major mathematical idea that can be vertically articulated through the K-8 curriculum and that connects to all curriculum strands (Number, Property, and Operations; Geometry and Spatial

Sense; Measurement; Patterns, Functions, and Algebra; Data, Probability, and Statistics)

- To involve teachers in a curriculum development process that is informed by Benchmark test data and moves teachers from a static, traditional model based on covering a textbook to a dynamic model based on student learning.

Each site visit consists of a planning session, a teaching session (either model-teaching by a mathematics educator or team teaching), and a reflection session. The goals of these visits are:

- To implement the curriculum written in summer institutes and integrate multiple Standards-based resources into plans and lessons
- To model inquiry-based teaching that not only develops higher order thinking skills in students but also assesses students' conceptual understanding
- To develop short written assessments of daily lessons that reveal student understanding
- To reflect on all assessment data (from daily written assessments to state tests) so that teachers will continually monitor and adjust the written curriculum.

To document the changes in teacher practice, we have collected teacher-made curriculum documents, lesson plans, student assessments, and observational and interview data from the classroom visits.

The way in which teachers combine content and curriculum is emerging as a most interesting aspect of the study. In the initial activities of the curriculum alignment process (Summer 2000), teachers could only list topics. They had trouble describing exactly what they taught about a topic. While some teachers reported that they felt responsible for covering too many objectives, others revealed that they repeated major teaching objectives that should be only revisited at their grade. Within this week, the teachers did begin to articulate conceptually based objectives for each grade. The discussions between different grade level teachers were invaluable. For example, an eighth grade teacher explained to a sixth grade teacher how she wanted her to informally introduce algebraic equations. A group of fifth grade teachers at Site 2 decided to find material that would emphasize the meaning of fractions and equivalence. Previously, they had emphasized rules and covered procedures for all four operations. The sixth grade group would use this foundation and extend their teaching to the operations.

While we have observed modest success in the curriculum writing process, we have found problems in the classroom. At Site 2, the third grade teachers resisted the written curriculum and returned to the former textbook. A dramatic fall in norm-referenced test scores for their students amidst gains at the other grade levels convinced them to implement the plans and resources they had opposed. They have seen differ-

ences in student understanding on a daily basis and have had gains in the Spring 2002 scores. At Site 1, the third and fourth grade teachers are no longer in the project. Their resistance is in part due to adherence to a textbook series. However, during the two years in PDCA, they did identify weak areas and found Standards-based resources for them.

The conflict between using the written curriculum and relying on the textbook also affects grades 5-8. In Summer 2001, the focus of the institute was proportional reasoning. In its report, *The Mathematics Education of Teachers*, the Conference Board of the Mathematical Sciences, recognizes proportional reasoning as a major set of ideas that permeates the middle school curriculum. Yet, teachers fail to recognize how this big idea connects the curriculum strands and instead focus on rules and procedures for fractions. While we documented gains in teacher knowledge at the institute and assisted with curriculum plans that we thought would circumvent typical problems, we did observe the same lessons on fractions at grades 7-8 as those being taught at grades 5-6. I watched an eighth grade teacher at Site 1 who relied heavily on the textbook and re-taught operations with fractions out of context (bare-number skill problems). Not only did her students not do well on an end of unit test, but it also seems she wasted many days re-teaching procedures when she might have had a better result with interesting problems in which students had to make sense of the numbers and operations. In a reflection session, this teacher reported that she would like to do something different. We decided that first we would investigate the fraction topic in grades 5-8 with the following questions for teachers in each grade:

1. What knowledge about fractions do your students bring to your class?
2. What weaknesses and misunderstandings do they bring?
3. What are your major teaching objectives for rational numbers?
4. Ideally what should your major teaching objectives be?

To summarize the responses, we found that teachers reported that student understanding does not change much from understanding basic fractions as parts of a whole. The fifth grade teacher realized she needed to do more with fraction concepts because she was "concentrating on decimals and place value." The seventh and eighth grade teachers were re-teaching the sixth grade objectives. The sixth grade teacher wanted to integrate fractions into lessons from all five curriculum strands, and the seventh and eighth grade teachers wanted to teach fractions in problem solving lessons.

After teachers reviewed these responses, model-teaching sessions were planned. The most effective work occurred with the sixth grade teacher who requested lessons from *Bits and Pieces II* in the Connected Mathematics Project, which is only supplementary material in this school. By being able to watch student interactions with a university educator in several lessons, she saw that a concept could be launched in

the context of a rich problem that would become a reference point for work done with fractions throughout the year. She also began to see tasks and lessons that were proportional in nature so that fractions could become a part of many lessons. Assessments were planned that would track student progress with fraction concepts.

In the short oral session we will present teacher responses to the fraction questionnaire as well as resulting revisions (Summer 2002) in the written curriculum and the sixth grade teacher's analysis of the fraction assessments and implications for her teaching practice. While two and a half years of work in PDCA has not produced the "perfect curriculum," it has produced groups of teachers who can identify problems, openly look for solutions, and make data driven decisions.

## INTERMATH - ENHANCING CONCEPTUAL DEVELOPMENT OF MIDDLE SCHOOL TEACHERS WITH TECHNOLOGY

Evan Glazer, Chandra Hawley Orrill, & Ayhan Kursat Erbas

University of Georgia  
intermath@coe.uga.edu

InterMath is an NSF funded initiative aimed at improving the conceptual understanding of middle school mathematics teachers. Teachers in InterMath participate in a workshop course that promotes mathematical exploration and problem solving using technology. InterMath content includes a series of mathematical investigations that require deep examination of middle grades mathematics concepts. Teachers create a web-based portfolio that includes essays about their investigations. In addition, teachers make connections of their learning to their classroom by designing technology-enhanced activities for their students.

InterMath (<http://www.intermath-uga.gatech.edu>) is an NSF funded, Web-based initiative. The InterMath environment engages teachers with technology-enhanced investigations in an effort to deepen their understanding of mathematical concepts related to the middle school curriculum.

InterMath seeks to encourage changes in teaching and learning based on the use of technology and the vision set forth in NCTM's standards. InterMath embraces the notion of mathematics as problem solving, reasoning, and communicating so that students are empowered to confidently "explore, conjecture, and reason logically [about the world around them]" (NCTM, 1989, p.5). This change in learning philosophy reflects a need for mathematics that is based in an information-rich and technology-based society. Learning goals should incorporate values that reflect mathematics for life, mathematics as a part of cultural heritage, mathematics for the workplace, and mathematics for the scientific and technical community (NCTM, 2000).

InterMath participants include primarily middle school mathematics teachers and workshop facilitators in the state of Georgia. Any middle school teacher or administrator in the state can participate in the InterMath workshops. Priority in participation selection is given to teachers that have introductory technology skills and those who can attend with peers from their school. Participating teachers can receive university credit or staff development credit for their involvement in the semester long workshop. The classes meet in three hour time periods, once a week, for a semester. During the class, the InterMath facilitator often models thinking, problem solving, and technology use of an investigation that is found on the InterMath website. Teachers are then provided considerable time to conduct their own mathematical investigations, often in teams. During this time, teachers are given an option to closely examine an investigation of their choice based on a particular concept discussed that day, such as fractions or graphing. Teachers use technology tools, such as spreadsheets, function graphers, and dynamic geometry, to support their thinking to develop and verify conjectures.

After using technology to test and verify their conjectures, teachers are encouraged to examine *why* they arrive at a particular finding, usually through proof or additional representation. Further, teachers are encouraged to extend their learning by posing related extensions to the activity so they can broaden their findings and make connections between concepts or to consider how they might be able to teach this concept in their middle school classrooms. Finally, teachers write up and display their findings in a web-based portfolio that can be accessed at the InterMath website.

The poster presentation will demonstrate InterMath investigations, describe the teachers' professional growth through InterMath workshops, and provide opportunities for others to use and contribute to InterMath resources for their own instructional purposes. The investigations will be shown from the presenters' laptop computer, giving viewers an opportunity to experience the dynamic environment that the technology-enhanced activities afford. InterMath teachers' web pages that reflect on these investigations will be shown to illustrate their problem solving methods, conceptual understanding, and lesson plans throughout the InterMath experience.

## ON BECOMING A REFORM-ORIENTED MATHEMATICS PROFESSOR BY REFLECTION

Kyungsoon Jeon  
University of Illinois at Chicago  
Ksjeon@uic.edu

The purpose of this study was to describe the process of change that a senior mathematics professor with thirty nine years of teaching experience had in his upper level course in secondary mathematics education under the reform influence of a faculty development program and to explain the role of *reflection* in the change process. The researcher had an opportunity to observe the professor's teaching practice for a semester and served as a support provider for him to sustain the change process during, before, and after the class through in-depth conversations based upon the observation of his classes in the fall semester. The method of teacher *reflection* was utilized for the teacher who wanted to bring change (Jalongo, 1992) in the on-going conversations between the professor and the researcher. Both the teacher and the researcher understood teacher *reflection* in the way as John Dewey (1933) described; *reflection* as "behavior which involves active, persistent, and careful consideration of any belief or practice in light of the grounds that support it and the further consequences to which it leads" (Grant and Zeichner, 1984, p. 4). This method of *reflection* addressed the professor's personal experiences as a teacher and their influence on shaping his teaching practice in a systemic way. The change in his beliefs about the nature of mathematics teaching was reshaped in conjunction with his understanding of learning represented by his students that he obtained through the *reflection* on his teaching. Even though the *reflection* process was a time intensive process, the process served as an encouragement and structure for the change to happen in his teaching practice. In this study, he was a professional who can make reasonable decisions, and the process of *reflection* served for him. Consistently, this study made a close connection between practice and research by influencing each other. Understanding his beliefs about the nature of mathematics teaching and many other different issues related to teaching practice helped the connection be established. For the connection between research and practice, the researcher tried to communicate with the teacher much insight about mathematics teaching practice that the reflective professor tried to implement in his mathematics course. The learning from the researcher's presence in the classroom where the practice of teaching was vividly experienced provided the professor with on-going feedback and this acted as a vital source for betterment of his teaching in practice. As the result of it, the professor continuously reshaped his teaching practice in the reform-oriented way. In addition, the learning through the communications was used as an importance vehicle for providing a continuing support for the professor's sustaining of the change. This connection between practice and research was signifi-

cant. I, as the researcher, learned the importance of the environment and support for a university faculty member to learn to be reflective about his teaching and about his students' learning. The professor, as the practitioner, became thoughtful through the reflective process so that he developed his own professional thinking and continued as a life-long learner with those many years of teaching experience. As he always put it, everything was developing in the process.

### K-3 TEACHERS' APPROACHES TO MATHEMATICAL ARGUMENTS

Ok-Kyeong Kim  
Western Michigan University  
ok-kyeong.kim@wmich.edu

Joy Whitenack  
James Madison University

Developing and evaluating mathematical arguments is one of the goals that students should reach while they are learning mathematics (National Council of Teachers of Mathematics, 2000). To develop these abilities, students need to have opportunities to engage in classroom activities that allow them to justify their own ideas and analyze others' ideas. They should be able to communicate and provide reasons for their ideas. As such, teachers need to provide their students with appropriate opportunities for making and criticizing mathematical arguments from primary grades. In addition, teachers themselves should develop their abilities of making and evaluating mathematical arguments.

In this presentation, we share elementary teachers' approaches to mathematical arguments while they were engaged in K-3 teacher professional development project activities during the 2000-2001 school year. During the project, 34 teachers had opportunities to define mathematical terms such as even numbers, rational numbers, what constitutes a straight line on a plane and on a sphere.

During the project, many different types of data were collected. For this report, however, we used transcriptions of class videotapes, field notes made of classroom observations, teachers' class notes (containing reflections and solutions to tasks), and telephone interviews conducted with eleven of the teachers. Our analysis not only clarifies how individual teachers reasoned about particular mathematical ideas, but also how their ideas were developed during discussions.

To analyze the data, we first condensed the data by coding, categorized emerging themes, and compared them. Finally, we looked for common themes. These steps, however, were not linear. We had to continue to revisit the original codes and earlier categories to see if there was a counter case and to look for the main themes related to the teachers' conceptions of mathematical arguments.

From data analysis, several common themes emerged among the teachers' approaches to mathematical arguments. First of all, for the teachers to be convinced, mathematical arguments needed to be something tangible or visible. They tended to reason using their everyday knowledge when they made and evaluated mathematical arguments. In such instances, they often discarded their previous claims, even when these claims had been made with full confidence. Second, not surprisingly, these teachers' knowledge of mathematics restricted their ways of developing and evaluating mathematical arguments. Their understanding of rational numbers and of mathematical terms, for instance, sometimes constrained how and when they developed

mathematical arguments. As we will illustrate during the presentation, some teachers were not sure that  $\frac{2}{3} = \overline{.6}$  because they thought that  $\overline{.6}$  did not fully represent  $\frac{2}{3}$ .

In addition, they were most comfortable with relying on other external sources to confirm their claims. In such cases, the teachers asked the instructors to just confirm the “rightness” or “incorrectness” of their ideas. That is, their ideas, and more generally the evolving collective arguments did not provide sufficient convincing power.

On the other hand, by engaging in these activities, the teachers had opportunities to experience what constitutes a mathematical argument as well as to develop ways to evaluate claims and provide reasonable explanations. They did not just take mathematical arguments as given. They wanted to be convinced of why the arguments worked or not. Even though some formal proofs offered by the course instructors made the teachers frustrated and confused, the proofs certainly challenged them to look at mathematical arguments in a different way. They also realized the importance of using precise language when they described mathematical objects and situations. While defining terms and evaluating others’ claims, they experienced that imprecise terms caused confusion and vagueness.

In conclusion, elementary teachers should have opportunities to engage in activities that allow them to explore and develop mathematical arguments and proofs. Such experiences can help teachers conceptualize or reconceptualize how they might guide classroom discussions that facilitate mathematical arguments. In so doing, their students may develop ways to participate in the argumentative process and ultimately, make “proofs” about certain claims.

## THE CHANGE OF TEACHERS' CONCERNS WHILE PARTICIPATING IN A SYSTEMIC PROFESSIONAL DEVELOPMENT PROJECT

Jo Clay Olson, Jeffrey Barrett & Graham Jones  
Illinois State University

This study investigated the extent to which elementary teachers involved in a systemic change project changed their practice during the first year of implementing reform curriculum using a concerns-based scale. Professional development focused on meeting teachers' immediate needs while engaging them in activities that would help them modify their practice. Researchers rated teachers on the personal, managerial, and collaborative concerns that arose during the implementation process. Results showed that teachers' concerns changed significantly over the first year. An ANOVA test indicated the concerns of teachers at different grade levels did not differ significantly. By addressing the concerns that arose during the implementation of reform curriculum, teachers at all grade levels were able to reflect on their practice and experiment with new modes of teaching.

The *Principles and Standards for School Mathematics* (NCTM, 2000) describe teaching and learning mathematics as a process in which teachers engage students in mathematical explorations and discussions. There is growing recognition that without sustained professional development, teachers do not implement new content, pedagogy, or assessment practices in their classrooms. The Primary Mathematics Education Project (PRIME) is a collaborative change initiative between Illinois State University and a large midwestern school district which established a sustained development program for the district. This study investigated the extent to which elementary teachers involved in PRIME changed their practice during the first year of implementation to reflect a reform vision of mathematics instruction using a concerns-based scale S and whether the grade levels taught influenced the adaptation of reform practice.

Previous research suggested professional development sensitive to the concerns of teachers encouraged generative growth and formed the theoretical framework for this study (Brosnan, 1994; Confrey, 1990; Hewson & Thorley, 1989; van de Berg, 1999). Professional development was designed to support collaborative learning communities where teachers discussed new teaching strategies. It was hypothesized that teachers would begin the innovation with concerns centered on how the innovation affected them personally and over the first year their concerns would change from a need for knowledge to concerns about the impact of the innovation on students.

### Professional Development

PRIME teachers followed daily routines typical of mathematics classes throughout the United States. The instructional goal for students was to solve problems quickly and accurately. Teachers assumed student understanding would evolve with

repeated practice. PRIME's overriding goal was to help teachers develop a reflective practice as they implemented *Investigations in Number, Data, and Space* (TERC, 1997) to improve K-5 math instruction. To meet this goal, PRIME extended teachers' mathematical content and pedagogical knowledge through summer institutes and school-year seminars, which linked theory with practice. Through reflection, Teachers critically analyzed the process of teaching and learning. A major focus of the project was to improve the questioning skills so teachers would (1) attend to student thinking; (2) use student thinking as a basis for instructional decisions; and (3) engage students in discourse. These efforts were reinforced with on-site visits by PRIME mentors throughout the school year.

### Method

Each semester, teachers participating in the PRIME Project scheduled three classroom observations with PRIME mentors. During each half-hour classroom observation, the classroom teacher and their mentor discussed the lesson's task and the use of questions to develop students' mathematical thinking. To appraise the change of teachers' practice during PRIME, the concerns-based adoption model (CBAM) (van de Berg, 1999) was utilized to document the concerns teachers held toward innovation during implementation. The CBAM describes three clusters of concerns with 7 stages: self concerns (stage 0-little concern, 1-need for information, 2-consequences for students); task concerns (stage 3-management); and other concerns (stage 4-collaboration, 5-revision, 6-exploration of benefits). The mentors rated each teacher in October 2000, April 2001, and October 2001.

### Results

A paired sample  $t$  test was conducted to evaluate whether teachers' concerns changed during the first school year of implementation. Using .05 level of significance, the results indicated the mean change (.60) during the first school year was statistically significant,  $t(100) = 9.67, p = .001$ . The mean change (.12) during the summer was not statistically significant,  $t(100) = 1.01, p = .31$ . During the first year of implementation, the mean change (.70) was statistically significant,  $t(100) = 5.50, p = .001$ .

A one-way analysis of variance was conducted to evaluate the relationship between teachers' grade levels and their implementation of reform practice. The independent variable was the grade level taught by the teacher and the dependant variable was the CBAM rating. The ANOVA test showed there was not a statistically significant difference between groups  $F(4,96) = 1.09, p = .37$  for October 2000 or October 2001,  $F(4, 96) = .41, p = .80$  and the relationship was moderately weak,  $O^2 = .29$ . While the ANOVA test indicated grade levels did not differ from each other for the time periods, review of the mean level of concerns for teachers at different grade level suggested trends of concerns for the grade levels might differ. A paired sample  $t$  test was conducted to determine whether grade levels concerns changed in similar

patterns. K - 3 grade level teachers showed a significant change of concerns over the school year and fourth grade teachers showed significant change of concerns over the school year, during the summer, and during the first year of implementation.

### Discussion

This study investigated the extent to which teachers changed their concerns during the first year of reform curriculum implementation. Initially teachers mean CBAM score was .66, indicating a limited awareness of reform teaching practice. A year later the mean score was 1.37 suggesting that teachers shifted their concerns from an awareness to interest in gaining more information and its impact on developing student thinking. Not surprisingly, the teachers showed the most growth during the school year when they could put into practice the ideas discussed during the seminars. Each semester, teachers were assigned a reform lesson to use with students for discussion at the school year seminars. These assignments and meeting with PRIME mentors supported teachers as they considered the consequences of the intervention on their personal teaching practice and student learning.

Based on the CBAM, ratings, teachers in the PRIME Project were struggling to make sense of how reform teaching affected them personally and its consequence on students. Webb, Heck, and Tate (1996), and Confrey (1990) described the process of teacher change to be slow, as teachers first must understand the nature of the change. As teachers reflected on the plausibility of the endorsed changes, they reassessed its usefulness and decided the degree to which they would adopt the changes. This study supports a description of the change process as a rocky road, to be traveled slowly and carefully negotiated. Hewson and Thorley and Pfaff (2000) found that critical reflection, dialogue, and collaboration between teachers was critical for change to become systemic. With continuous opportunities for critical reflection during the school year, teachers' concerns changed. Without these supports during the summer, teachers reverted to previous concerns. By addressing the concerns that arose during the implementation, teachers reflected on their practice and experimented with new modes of teaching.

## **THE ROLE OF LISTENING IN ONE TEACHER'S ENVISIONING AND IMPLEMENTATION OF AN EMERGENT MATHEMATICS CURRICULUM**

Stacy Reeder  
Oklahoma State University  
stacyreeder@worldnet.att.net

Envisioning alternatives for education is a difficult and complex task often met with challenge from outside forces and influences and sometimes even hampered by our own inability to imagine that something else is possible, an inability to see beyond the current and traditional ideas about education. Dewey, a century ago, identified this as our inability to see beyond the oscillation between the extremes of "forcing the child from without, or leaving him entirely alone" (1902, p. 195). The purpose of this study was to examine the pedagogic practices of one middle school teacher who has "seen" an alternative. He has envisioned and enacted an emergent mathematics curriculum in his classroom with and for his students. As his story of transformation unfolded the important role of listening for this teacher became apparent. Listening to his students became an inherent and integral part of the process of his evolution as he initially tried to transition from traditional pedagogic practices to a problem centered learning approach to teaching mathematics. The results of this study reveal the importance of listening as this teacher developed as a constructivist teacher and now as he participates with his students in an emergent mathematics curriculum. Hermeneutical listening, as described by Davis (1997) occurs when the teacher becomes "a participant in the exploration of ... mathematics" (p. 369). This teacher participates, listening from a hermeneutical perspective, in a flow of conversation with his student that is not predetermined or controlled by lesson plans or teacher perceived outcomes. This conversation is driven by his, and often the students', presentation of worthwhile mathematical tasks, problem centered inquiry, and hermeneutical listening. This poster will present a portion of data collected for my dissertation research which was a larger study focusing on two teachers and their enactment of an emergent mathematics curriculum. The role of listening as described above was one aspect of the middle school teacher's case that emerged. The larger study was designed as a qualitative case study employing a narrative inquiry approach and a constant comparative method for data analysis throughout the study. The data collected for this study included classroom observations and field notes, video-taping of class sessions, extensive audio-taped interviews with the participant teacher following each class session, and a variety of classroom documents (i.e., problem solving tasks, assessment, and class syllabus). Data was collected over the period of six months during the school year.

## **History and Aims of the PME Group**

PME came into existence at the Third International Congress on Mathematical Education (ICME 3) held in Karlsruhe, Germany in 1976. It is affiliated with the International Commission for Mathematical Instruction.

The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education.
2. To promote and stimulate interdisciplinary research in the aforesaid area with the cooperation of psychologists, mathematicians and mathematics educators.
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implementation thereof.

## Preface

It is with great pleasure that we at the University of Georgia host the 24<sup>th</sup> annual meeting of PME-NA as we also hosted the 4<sup>th</sup> annual PME-NA meeting exactly 20 years ago in 1982. A quick glance at the differences between then and now shows how the field has grown and changed: The proceedings that year were about 250 pages long, and there were 34 papers presented in 7 topic areas. This year the proceedings will be nearly 2000 pages long with over 200 presentations in 15 topic areas. Despite the growth of the field and the organization, the hallmarks of collegiality and open intellectual exchange remain.

The theme of this year's conference is *Linking Research and Practice*. The theme is intended to highlight the interplay between the ways that research is used in practice and the ways that research grows out of practice. The invited plenary speakers were asked to address the theme in their areas of expertise by challenging the audience to think critically about the research we do—the questions we ask, the methods we use, the contexts in which we do research, the people with whom we do research, how we communicate the results of our research, etc. We hope that those in attendance as well as those who will read these papers in years to come will be stimulated to think deeply about our roles as researchers and consumers of research.

We received over 250 proposals for sessions at PME-NA and are grateful for the work of the many reviewers who helped shape the program. We undertook only structural editing (format and references) on the final papers so as to leave intact the integrity of the authors' work.

We wish to express our appreciation to the many people at the University of Georgia who have made these volumes and this conference a possibility, including, but not limited to, Patricia S. Wilson, Margaret Caufield, Elizabeth Platt, Salli Park, Bernice Peters, Teresa Banker, Nancy Williams, Joseph Allen, Brian Wynne, and all of the faculty and graduate students in the Department of Mathematics Education.

*The Editors*

# **A LENGTH MODEL OF FRACTIONS PUTS MULTIPLICATION OF FRACTIONS IN THE LEARNING ZONE OF FIFTH GRADERS**

Karen C. Fuson  
Northwestern University  
fuson@northwestern.edu

Mindy Kalchman  
Northwestern University  
m-kalchman@northwestern.edu

We developed and implemented a curricular unit concerning operations on fractions. The unit used drawings of lengths fractured into equal parts for all operations. Students initially had 2 interpretations for multiplying by a unit fraction (i.e.,  $1/n$ ), one that generalized and one that did not. The predominant method, dividing by equal shares, did not generalize when the denominator of the unit fraction did not divide into the whole number evenly. The second interpretation, which did generalize to a unit fraction or a non-unit fraction times any whole number, was taking the unit fraction of each "1" (or single unit) in the whole number and then finding the sum of these products. The class and teacher then extended this second method to multiplying a fraction times a fraction, relating via written and oral explanations the length drawings to a general written algorithm of multiplying the top numbers and multiplying the bottom numbers. Students outperformed samples of U.S. students using traditional textbooks and Japanese and Chinese fifth graders.

## **Purposes, Perspectives, and Theoretical Framework**

Multiplication of fractions is on the Grade 5 curriculum in many states, but tests indicate that most U.S. students using traditional textbooks cannot solve such problems (Stigler, Lee, & Stephenson, 1990). Most East Asian students also do not solve such problems accurately (Stigler, Lee, & Stephenson, 1990). The question then arises whether this topic is developmentally inappropriate or whether the usual approaches to such teaching are not effective and fifth graders could learn with an effective approach.

A common visual representation of fractions used in instruction is a circular (e.g., pie, pizza) model of fractions (for discussion see, for example, Behr, Harel, Post, & Lesh, 1992; Clements & Del Campo, 1988; Lamon, 1999; Moss & Case, 1999). Pies and pizzas are within the experiences of most students, but both the real-world objects and the circular drawings of fractions frequently violate the central characteristic of fractions: fractions must have equal parts (equal shares). It is not easy to divide a circular model into equal parts except for 2, 4, and perhaps 8 parts. Examples of errors in circular drawings made by students at the beginning of the present study are given in Figure 1.

We instead propose a length model as a generalizable model that is easier to partition into an arbitrary number of equal parts and that will support all of the concepts and operations on fractions. Length models are also good for decimals and

Figure 1. Unequal fractions in student circular models.

for metric measurement, so they would also enable fractions to be related to decimals and metric lengths. In this paper we focus on multiplication of fractions, and we examine whether a length model will pull multiplication of fractions into the learning zone of fifth graders.

Our theoretical framework uses both a Piagetian constructivist model of learning and a Vygotskiiian socio-cultural model of teaching. From our Piagetian perspective, we assume that students are continually interpreting their classroom experiences using their own conceptual structures as well as continually adapting their conceptual structures to their on-going classroom experiences. From our Vygotskiiian perspective, we assume that a major goal of school mathematics teaching is to assist learners in coming to understand and use cultural mathematics tools. One means of assistance is drawings, which are semiotic tools that can support sense-making both individually and in the classroom discourse about mathematical thinking.

Our research question is whether our length models fit the learning zones of fifth graders well enough that length model drawings can be used to develop general methods of multiplying with drawings, which can be related to general numerical methods for multiplying fractions. This study is part of a larger project 1) examining the utility of the length model for helping students build understanding of all the concepts, situations, and operations involving fractions, 2) seeking to identify

students' general learning paths when using a length model, and 3) understanding how this approach to fraction understanding relates to concepts in other multiplicative domains (e.g., functions and ratio and proportion).

### Methods and Data Sources

Participants were 25 fifth-grade students in a classroom in a mid-western multi-racial small city with a considerable number of immigrants, a large minority of the students on free lunch, and a substantial number of students with highly-educated parents. This diversity was chosen to test the accessibility of our approach to a broad range of students.

The teacher, Ms. H., was an experienced teacher of reform mathematics who was recommended by a district-wise administrator for the quality of the mathematical discourse in her classroom. Working with such a teacher ensured that instruction would involve sense-making by all students and that alternative student methods using the length model drawings linked to numerical methods would be discussed. The students used the *Everyday Mathematics* curriculum as their regular mathematics program and were used to discussing their methods.

The present fraction unit was developed by the authors as an alternative approach to the one suggested in the *Everyday Mathematics* curriculum. In total, the fractions unit involved approximately an hour a day of class-time for a total of 15 days. Four days were spent on the multiplication of fractions. These days are described below in the results and conclusion.

The authors co-developed the initial version of the multiplication of fractions approach. The second author and Ms. H. met regularly to discuss the ideas in the approach, to address any concerns of either of the authors or of Ms. H., to make any necessary changes to adapt the unit to district goals and classroom idiosyncrasies, and to assess and adapt to on-going student progress. The second author, who is also an experienced elementary teacher, went to each class, videotaped each class, and contributed to the instruction and discussion when appropriate. The students understood her to be a co-teacher of the unit and someone with whom they could talk, of whom they could ask questions, and from whom they could seek help.

Data for analysis of the classroom instruction were videotapes, notes taken during and after class, and copies of the overheads made by Ms. H. and students during class discussions. Data for student learning were interviews of target students, students' work, and a test given at the end of the unit. This test was comprised of numerical items comparable to and word problems identical to those given by Stigler, Lee, and Stevenson (1990) to U.S. fifth graders using traditional textbooks and to Japanese and Taiwanese fifth graders. The test included items on most fraction concepts and was given 5 days after the multiplication teaching was ended and following one day in which all of the concepts were reviewed.

## Results

On the first day, students' methods were elicited for simple multiplication problems in which a unit fraction would divide a whole number evenly (e.g.,  $\frac{1}{3} \times 6$ ). Students had two different interpretations of such fraction times a whole number problems (see Figure 2). Some students used an equal sharing notion of multiplying by a unit fraction. They found "one-third of (the whole group of) 6" and so divided 6 into 3 equal groups of 2. Others found "six one-thirds" or "six one-thirds of one" and

then accumulated these thirds numerically or on a length drawing to get six thirds, which totaled 2 (thus 6 was formed by two groups of 3 thirds).

Instruction then moved to more difficult problems in which the fraction did not divide the whole number evenly. Students were unable to extend their own methods to these more difficult kinds of problems because most of their initial methods depended on the idea of a fraction as the equal sharing of a whole number. Students could not proceed if the fraction did not divide the whole number evenly. Using the length model, the piece-by-piece multiplying method that had arisen on Day 1 for  $\frac{1}{3} \times 6$  (see bottom of Figure 2) was extended first to a fraction times a whole number (Day 2) and then to a general fraction times a fraction case on Day 3. Each of these extensions was made in a whole-class co-constructing session led by the teacher with considerable input from students. Students then chose their own "fraction times

Figure 2. Student Length Models showing 2 interpretations of the Meaning of  $\frac{1}{3} \times 6$ .

An example of a student explanation at the overhead projector of multiplying a fraction times a fractions is as follows:

JT: Here's my fraction, four-fifth times two thirds (writes  $4/5 \times 2/3$  on a transparency). So I'm going to draw a line five segments long...(draws a horizontal line five inches long and places hash marks at each inch along the line). So now that I've labeled my fifths I'm gonna divided them each into thirds (places three evenly-spaced hash marks between the five-fracturing hash marks he drew previously). So I divided each fifth into, I divided it into thirds. [So now JT has done  $1/5 \times 1/3$ , the bottom part of the algorithm.] Now I have to circle four-fifths. That's the number of parts I have. Four-fifths is my fraction, so I circled that (retracing the large circle he made around four-fifths of the original line). Um...so now I have, I have to circle every two thirds (pause) because I have two-thirds times four-fifths. I circled the four-fifths, now I have to circle the two-thirds (pause). And you don't circle past the circled part (referring to the large circle around four-fifths). That's your extra. You don't need that. If you count every third, one, two, three (pointing to hash marks on his line) every, um, three thirds.

Ms. H: And you have five sets of three thirds? [seeking to get explicit naming and labelling of the common fracture:  $1/5 \times 1/3 = 1/15$ ]

JT: Ya.

Ms. H: Which is a total of how many spaces?

JT: Fifteen.

Ms. H: Fifteen for your whole, right? For your whole unit.

JT: So, I totaled my whole and that was fifteen (writing "15" below his line). So now I already circled it [the two-thirds] so I have one, two, three, four, with two in each (pointing to circled sets of  $2/3$ ). Four times two equals eight (writing the equation vertically) and you have to multiply that because you labeled it two-thirds. You circled two-thirds for each one. You have four sets of two-thirds. [explaining the meaning for the top part of the multiplication algorithm] With two in each and that gives you a total of eight (writes 8 above the 15 he wrote earlier).

The fourth day focused on doing more examples and discussing why the algorithm of multiplying top numbers and multiplying bottom numbers worked. These explanations were related to the fracturing experiences students had when making the drawings, for example, "For the bottom, you fractured one fraction by the other fraction, so you get a fraction that is their product; for the top, you are taking the top number of groups of the size of the other top number, so again you multiply."

Over the 4 days in which students drew length models of fraction multiplication problems, almost all students were able to make such drawings correctly. Some required help along the way with various steps, and not all students could explain all of the steps as clearly as did the student in Figure 3 or at the overhead. However, all students were using the length models with most of the steps drawn correctly and linked to accurate numerical labeling.

The students did very well on the multiplication items given at the end of the unit (see Table 1). More than 80% of our length-model students solved the numerical fraction computation problems correctly, compared to means of 20%, 21%, and 14% in Japan, Taiwan, and the U.S., respectively. Our length-model students also did comparatively well on the word problems, with 63% correct answers compared to 54%, 49%, and 20%, respectively.

Comments by students during whole-class discussion and individually indicated that particularly powerful parts of the length model seemed to be its generality (students could choose their own fraction times a fraction problem and draw it with the length model), its affordance of seeing and writing multiplication as repeated addition (see the  $3/28 + 3/28$  in Figure 3), and the visual ease of the connections of the partitionings in the length model to the multiplications in the numerical algorithm.

**Table 1.** Percentage Correct on Multiplication Problems by Students in Japan, Taiwan, and the United States

| Item   | Background of Students |        |                     |                         |

### Conclusions

Multiplying fractions by fractions is within the learning zone of fifth graders if a length model and a piece-by-piece partitioning method is used in a sense-making classroom environment in which drawings are referents for discussions and explanations of student thinking and the multiplying tops and bottoms algorithm is based on experience with these drawings. The piece-by-piece multiplying method works because one can gather the unit fractions into any mixed number (e.g.,  $1/3 \times 7$  instead of  $1/3 \times 6$  is just one more  $1/3$ , i.e.,  $2 \frac{1}{3}$ ). The length drawings for a unit fraction times a whole number (e.g.,  $1/3 \times 6$ ) are the same as those for a unit fraction times a unit fraction (e.g.,  $1/3 \times 1/6$ ) except that the labelling is different (labelling 1 through 6 instead of  $1/6$  through  $6/6$ ). This similarity simplifies the transition from multiplication by a fraction  $\times$  whole numbers to fraction  $\times$  fractions.

A recurring issue throughout the unit is why does “of” mean “times”? Students had no trouble understanding “one-third of 6” as dividing 6 into 3 equal parts, but this experience then made them think that they were dividing, not multiplying. In fact, multiplying by a unit fraction is dividing by that whole number, but the operation *within fractions* is multiplication. Either multiplication grouping or comparing language can provide a basis for understanding why “of” means times for fractions as well as for whole numbers. Across different countries, people interpret  $4 \times 2$  in two ways: as “4 sets of 2” or as “4 taken 2 times.” Using both of these meanings relates “of” and “times” within the English language. So  $4/5 \times 2/3$  can mean “ $4/5$  of  $2/3$ ” or “ $4/5$  taken  $2/3$  times.” Within multiplicative comparing situations, English shifts from the “times as many” to “fractional parts of” language, again providing a relationship between these two. For example, we say, “Joe has 3 times as many as Mary has” but “Mary has  $1/3$  of Joe’s amount.”

Finally, we wish to highlight our view that 4 days is not sufficient for mastery of fraction multiplication. These days were part of a larger coherent approach to fractions using length drawings. Follow-up work would also be necessary to maintain the understanding built during this unit. We see three phases in building understandings in such a complex domain. First, the domain is approached using intuitive easy numbers in situations where objects or drawings can help students develop meanings. Second, these meanings are connected to generalizable numerical methods through discussion and linking to drawings. Third, a longer period follows of remembering and explaining in which occasional practice with numeric methods by students is accompanied by explaining why the method works. This phase is required to keep the meanings connected to the general numeric meanings. The first phase must be done with a view to the second and third phases. We have seen in this study how the use of easy intuitive numbers that divided easily led students to methods of multiplying by a unit fraction that did not generalize to numbers that were not evenly divisible. Curriculum development must keep all of these phases in mind from the beginning if students are not to be led to develop methods that will not generalize.

## **CONCEPTS OF RATIO AND PROPORTION IN BASIC LEVEL STUDENTS: CASE STUDY**

Elena Fabiola Ruiz & Marta Elena Valdemoros  
CINVESTAV-IPN, México

This research report shows two of the three cases which were used to conclude and evaluate the advances achieved within a broad qualitative field work. The study was conducted among eleven-year-old students in a public primary school of Mexico City. The main issue in this research is the enrichment of the conceptual contents in both, ratios and proportions, related with the strategies employed in problem solving. Said cases are analyzed starting from the recognition of the identifiable profiles in both subjects through the interpretation of the results obtained in a teaching program carried out with the group of students they belonged and with two questionnaires applied before and after the instruction process. The follow up of these cases was done in three interviews of didactic nature. These interviews made up the prime methodological study instruments, which are part of a doctoral study to be concluded soon.

### **Theoretical Background**

For Piaget (1978) the notion of proportion always begins in a qualitative and logical fashion before its quantitative structure. In a similar way, Kieren (1988) highlights the transition from concrete to abstract, pointing out that the intuitive part is not totally left out. The aforementioned allowed to carry out the teaching proposal and the case studies here shown because it brought about a cognitive, global and evolutive point of view.

Karplus (1983) has been one of the first researchers to categorize the subjects' answers in problem solving, not as indicators of a general development phase, but as illustrative of a proportion comprehension level linked to teaching. This author also establishes that the additive reasoning does not lie in the beginning of a non-variant sequence of proportion construction, but that education strongly influences it and represents the student's effort to take on a task the best possible way there is instead of doing it systematically.

Hart (1988) describes different types of arithmetic problems through the recognition of several hierarchical levels of ratio and proportion comprehension. For this purpose, she resorts to children's methods of problem solving as the predominant errors and the respective mathematics contents. Hart was able to detect that most students found it easy to solve mathematics problems which dealt with proportion. Even so, there is evidence which points out that younger and high school students who are not very successful have a sense of what "looks right" or what "seems to be a distortion". For Hart, some generalization levels such as ratio solving and the methods to create equivalence relations are brought about when the multiplication strategies are used systematically. The didactic program and the case study presented here makes emphasis on it.

The other researches taken into account such as Freudenthal (1983), Streefland (1984, 1991) and Coll (1990) had the main purpose of combining the didactic aspects and the mathematics reflection about the elemental school teaching of ratio and proportion. From this base the instructional program was designed. The mentioned program was applied in the doctoral study partially exposed here.

In this way, the students were encouraged to work with the idea that the multiplication operator was only a support resource for the generation of “internal and external ratios” (according to Freudenthal, 1983) in regards to the proportional variation problem solving due to the fact that, in order to obtain the missing quantities in a table, several pupils made multiplications or divisions using a “scale factor” or “factor-function”, according to what Vergnaud (1991) stated.

### **Research Problem**

Using the developmental, cognitive, mathematical and didactic approaches which were fully explained in the previous section, a constructivist focus is adopted. Thus focus grants a privilege to the highly active role exerted by the sixth grade students when constructing the meanings, notions and concepts of ratio and proportion in the field of arithmetic problem solving using different representation registers, specially drawings, tables and numbers.

### **Method**

The study of the two cases shown in this work is part of the doctoral investigation near its formal conclusion. Through the follow up of some cases, the field work came to an end, with the purpose of conducting a deep assessment of the teaching within a school group (Ruiz, 2000, 2001; Ruiz & Valdemoros, 2001a, 2001b).

### **Methodological Instruments**

The following instruments were employed for the study: an exploratory questionnaire, the constructivist-didactic teaching program, a final questionnaire and three interviews of “didactic-nature” (according to the bases given by Valdemoros, 1998).

### **Questionnaire**

The “initial questionnaire” was later introduced as a “final questionnaire”. What changed between the both of them was the aim of its application; the first showcased a clear explanatory nature and the second was more focused on evaluation. The resolution space between one and the other was of seven months and was subject to a qualitative analysis of the results in both applications.

It was made up by 13 tasks. In some problems, justifications supported on the qualitative interpretation were required, since it was interesting to see the way in which thought is constructed without the use of quantities related to ratio and proportion. For another problems, it was necessary to do a drawing against the grid with

the sole purpose of achieving a transition towards quantification. The remaining tasks were explicitly quantified because some values were needed and some others were provided. For some of these tasks, a table was used as a way of representation for the recognition of internal or external ratios.

### **Teaching program**

This proposal dovetailed with current scholar of Mexico City. It was made up by eight teaching models used in different sessions, taking into account the definition related to the "teaching model" given by Figueras, Filloy and Valdemoros (1987). The teaching proposal started from the qualitative side, so that the student would be able to find sense and meaning to the ratio and to the proportion, gradually making the transition from qualitative to quantitative. All these without setting aside the qualitative level of thought at the end of said process. The transition was obtained by the application of several teaching models in different instruction sessions.

In the quantitative field, the student established relations between magnitudes, worked with natural numbers and they also used fractional expressions, making an elemental incursion into the field of rational numbers. The student was able to define the ratio as the relation between two magnitudes and proportion as the equivalence relation between ratios. These coincides with the definitions provided by Hart (1988).

### **Didactic-nature interviews**

Three girls from the sixth grade teaching study group were interviewed. They were picked based on their performance when taking questionnaire and during the teaching program. The interviews showed a natural and semi-structured character. Each one of the participants was subject to tasks of common design, similar to those included in the teaching proposal, in such a way that once finished, the results from all three cases were able to be compared.

The Snow White and the Seven Dwarves Model was used for the first interview (with newer tasks than in previous programs). Said model allowed to work with the issues regarding the student's qualitative and quantitative thought in the field of proportion. They intended to see up to what point the students were able to keep consistency in both thoughts, as well as verifying the fluency they displayed in the transition from one representation register to another: the drawing, the table and the numerical, checking their conceptual and semantic skills.

The main purpose for the second interview was to double check if they used ratios in their problem solving, and if so, weather they chose internal or external and why. Verifying the scope that the children gave to the concepts of ratio and proportion was of utmost importance. This was reflected in the way they interpreted said terms and their notation registers.

The third interview allowed to dig deeper into the way the subjects establish an equivalence relation based on ratios determination. At the same time, the usage of the

105

table was checked for its filling and for the relation between the table and the stated situation. There was an enrichment of the conceptual handling follow up, the basic technical language and the different representation registers added during the previous teaching process.

The didactic nature of the interviews was determined by the succession of two moments differentiated during the process: a) an initial program assessment phase in which the advance of each subject by his or her own means was determined and, b) a subsequent phase of constructivist-didactic nature, when the interviewer tried to encourage the interviewed to overcome the cognitive difficulties shown in his or her previous development, providing a feedback to it, but doing without solution proposals and without obstructing new searches by the student. The interview was a fundamental instrument in the development of this case study.

### **Subjects**

The students involved in the doctoral research were 29 eleven-year-old children, attending sixth grade in primary school. We present two of the three case studies in this work: a) the case of Nuria, who showed characteristics common to a certain sector of the school group, identifiable by the ease with which they used any of the three modes of representation (drawings, table and numbers) when solving the problems, and b) the case of Wendy who showed a poor initial scene, but achieved tremendous breakthrough. This situation was also acknowledged by her classmates.

### **Result Analysis**

We highlight the follow up of the representation modes adopted by both girls, the ease and difficulties related to the usage of internal and external ratios as well as the establishment of proportions. The contents that Nuria and Wendy gave to the concepts of ratio and proportion, the argument with which they supported the respective processes of problem solving.

### **The Case of Nuria**

Before the teaching program Nuria did not know the concept of ratio, since it was not included in the school's program; *after the didactic program*, she was able to give meaning and sense to the terms of ratio and proportion.. In the *questionnaires* and in the teaching program, Nuria used several strategies in order to solve them.

During the interviews and in regards to qualitative issues, she used verbal categories such as, "bigger than..." or "smaller than..." When dealing with tasks related to the transition from qualitative to quantitative, Nuria worked with number extension, once she detected the factors for the corresponding scale (x2), (x3) and for the cases of reduction she divided between two or three.

In those tasks demanding the filling of tables, she was able to do so multiplying by the natural operators which she determined by watching how the values increased

in each column. To solve other tasks, in the quantitative field, first she obtained the unitary value to determine what she was asked. The language she used to express herself was somewhat technical sometimes, when using words such as “a half”, “double” and “triple”. She showed a good usage of concepts and an ease to employ symbols and terms loaded with meaning in different work sessions. This was reflected in the way she solved the tasks through the establishment of relations in both, the qualitative and quantitative fields. All this led her to determine ratios within different contexts, as well as the equivalence relation between them, to finally arrive with success to the solution of the stated situation.

She managed to use the three types of representations: the drawings, the table and the numbers, she could also make the transition from one to another. At no time did she leave out the qualitative, despite working with the quantitative, because for all her explanations she used ratios and proportions through the fractional notation and through the use of the table, but she also showed her intuitive and common sense ideas as a way of corroborating them. She could understand the concept of likeness as two figures which are proportional.

### **The Case of Wendy**

The girl showed great advance *after the teaching sessions*. In the *interviews* it was plain to see that she overcame the idea of “focusing” in only one dimension of the plane figures shown to her (thing which was deeply rooted in her at first), being able to extend or to reduce both linear dimensions of said figures. She was able to give sense to the algorithms she used to solve the proportion tasks. She used ratios and proportions adequately, getting them from the table or from the text of the problems were stated in. She used natural or fractional operators to make the transition from one scale to another or from one value to another within the same scale. In regards to this, she showcased a clear command of halves and thirds but she acknowledged the existence of another fractional operators.

She used the table as a representation register since through it she was able to express ratios as fractions. This shows an important aspect of the great breakthrough achieved by Wendy, because at the beginning of the teaching program she had difficulty when extracting data from a table to give solution to the problems. She also gave signs of being unable to organize data provided in a table and to identify the ratios in it. After the didactic program, not only was Wendy able to compose ratios when interpreting and relating the magnitudes involved in the tables, but she was also able to express them with fluent fractional notations.

### **Conclusions**

The progress achieved by Nuria in the interviews, as the crowning of a whole process, were the integration of the different representation systems, the broad usage of all sorts of multiplication operators, the link of figure measurement with the estab-

lishment of proportional ratios, the use of ratios as fractional expressions and the elemental construction of the concepts of ratio and proportion.

For Wendy, the teaching experience in particular, made easier for her the use of proportional variation tables, the full sense granted to the multiplication operators (natural as well as fractional) and the active establishment of the ratio and proportion elemental concepts.

**WHEN “THE SAME” IS THE SAME AS DIFFERENT DIFFERENCES:  
ALIYA RECONCILES HER PERCEPTUAL JUDGMENT OF  
PROPORTIONAL EQUIVALENCE WITH HER  
ADDITIVE COMPUTATION SKILLS**

Dor Abrahamson  
Northwestern University  
abrador@northwestern.edu

The paper introduces the “eye-trick”, an optical illusion, and argues for its viability as a didactic means to mediate between young students’ naturalistic perceptual judgments and mathematical descriptions of proportional equivalence classes (e.g.,  $2:3=4:6=6:9=8:12=\dots$ etc.).

Cognitive-psychology (Suzuki & Cavanagh, 1998), biological (Thinus-Blanc, 1988), and developmental (Piaget & Inhelder, 1946) studies all suggest a human capacity to perform *perceptual* judgments of proportional equivalence, e.g., between two geometrically similar rectangles. Such performance appears to rely on what Cobb and Steffe (1998, p. 55; see also Gelman, 1993) call “concepts in action, enactive concepts, rather than [on] abstract concepts embodying a structural relationship between...quantities”, as evidenced in students’ notoriously low achievement in *numerical* proportion problems (e.g., Kaput & West, 1994). By embracing students’ domain-appropriate ‘enactive’ knowledge, we hope to create “instruction [that] is in harmony with [learners’] schemes” (Cobb & Steffe, 1998, p. 48), and may thus preempt “discontinuities between the child’s procedures and the child’s concepts” (p. 58; see also Vygotsky, 1978; and Freudenthal, 1981, on mathematization). Specifically in the domain of ratio and proportion, the “eye-trick”, a perceptual illusion (see below), may afford students an opportunity for “logico-mathematical structuration that....*goes beyond perception*” (Piaget & Inhelder, 1969, p. 49, my italics).

The motivation of this work is our belief that ratio and proportion is an advantageous conceptual entry to rational numbers (e.g., see Confrey, 1998) because ratios do not require embedded numbers, as fractions do. Fractions are *parts-to-1-whole*, and thus present the perceptual-logical challenge of ‘inclusion’ (e.g., Singer & Resnick, 1992). The simpler visual physical instantiations of *whole-to-whole* ratios in geometrically similar shapes suggest a simpler approach. This work was done as part of our larger project to utilize the multiplication table as a source for teaching/learning rate, ratio, and proportion as coming from iterated addition (see also Abrahamson, 2002; Cobb & Steffe, 1998; see Abrahamson & Cigan, 2002, for an outline of our curricular unit).

### Method

The eye-trick involves two proportionate pictures (e.g., of heights 2cm&3cm and 4cm&6cm, Figure 1a). Children are asked to shut one eye to eliminate their stereo-

Figure 1a. Cards A and B as seen laid flat on the table.

Figure 1b. Cards A and B as seen through the eye-trick illusion.

scopic vision. Holding both pictures, they then move the larger picture away from the smaller picture (farther from their eye) until they find a point where the two pictures produce images of the same size (Figure 1b). This proportion is then examined numerically by attending to the embedded ruler in each image (2&3 units in both pictures), and through measurement, using a stretchable rubber ruler. The unstretched units of this ruler correspond to 2 and 3 units of height in Card A and to 4 and 6 units of height in Card B, but the stretched units of the ruler correspond to 2 & 3 units in Card B. The entire set of materials included a total of five cards per ratio set (e.g., 2:3, 4:6, 6:9, 8:12, 10:15) as well as additional sets of cards (a 3:4 set and a 3:5 set) bearing different images of object pairs.

We have employed the eye-trick tasks both in whole-class design studies (Abrahamson & Fuson, in preparation), and in clinical interviews, of which Aliya's (8.5-year-old) interview was typical. I worked with and video-taped Aliya over three 1-hour periods spanning 15 days.

### Results

Aliya (a) saw that two cards of different size appeared "the same"; (b) measured these cards with the stretchable ruler and tabulated these data (2&3, 4&6, in Figure 2a); (c) claimed these data were mathematically nonsensical since  $3-2=1$  but  $6-4=2$  (the differences are different); (d) sought an alternative numerical pattern to explain what she saw, wondering aloud whether the differences of 1 and 2 units, respectively,

could possibly signify a trend of 1, 2, 3, etc., which would predict a difference of 3 in an additional card; (e) explored and verified her hypothesis by using a card in which the relevant dimensions were 6cm:9cm (6 & 9, Figure 2a); (f) compared these data to a case of head-start equal-rate growth (Figure 2b, Bob and Joe were born exactly one year apart); (g) discussed the viability of each table as a mathematical descriptor of some real-world class of situations; (h) practiced using her hands to simulate and differentiate equal-rate and different-rate growths: starting from holding her hands 2 and 3 “units” above the table, respectively, she raised her hands whilst either maintaining a fixed difference between them or by gradually increasing the difference; (i) re-interpreted the proportion table as modeling “unit-splitting”, e.g., 3 “becomes” 6 because each 1-unit became 2 smaller units but the visible total remained the same size (Fig. 3, compare to  $2 \times 3$  as  $3+3$  where the total visibly doubles in size); (j) came to accept proportional equivalence as the numerical phenomenon corresponding to the stretch/shrink or “change unit” classes of real-world situations.

| Head-Start<br>Equal Rate |     |
|--------------------------|-----|
| Bob                      | Joe |
| 2                        | 3   |
| 4                        | 5   |
| 6                        | 7   |

Figure 2b. Sibling ages.

### Conclusions

The eye-trick provides a powerful sensory support for understanding proportional equivalence. This visual support was successful in overriding the well-documented “additive frame”, by which  $2:3$  cannot equal  $4:6$  because 3 is 1 more than 2 but 6 is 2 more than 4. It enabled Aliya to build an additive-multiplicative frame for proportion situations, initially as additive increasing-difference situations (within the ratio-table rows), and then as a multiplicative interpretation of unit splitting within both the eye-trick pictures and the ratio table (between its rows).

Figure 3. Explaining proportional equivalence as coming from unit-splitting interpreted multiplicatively.

**UNITIZING: THINKING IN PACKS AND PIECES**

Teruni d. Lamberg  
Vanderbilt University  
Teruni.d.lamberg@vanderbilt.edu

James Middleton  
Arizona State University  
James.Middleton@asu.edu

The purpose of this report is to examine how fifth grade students in whole class teaching experiment conceptualized and symbolized a problem containing composite units. The analysis presented in this paper is significant because it sheds light on students' unitizing and reunitizing processes as they solve a fair sharing problem containing composite units. The findings from this study indicates the importance of having students symbolize and explain their thinking as they work with composite units through pictorial representations. It forces students to explicitly think about the shifting nature of the unit as they decompose the original unit and reunitize to solve fair sharing problems.

The ability to form reference-units based on the problem context and the capability to flexibly decompose the unit and convert it into different forms while problem solving is important for working with rational numbers. This process is called unitizing (Lamon 1993, 1999). It is a cognitive process for conceptualizing the amount of given commodity or share, before, during and after the sharing process (Lamon, 1996). A unit can signify one continuous object, a set of discrete objects or a unit of measure (Behr, Lesh, Post, & Silver, 1993). Once a reference unit has been determined based on the problem context, it can be decomposed into smaller chunks through partitioning and recomposed while problem solving. Students have more difficulty reuniting the decomposed pieces into different size chunks as opposed to being able to decompose the whole into smaller parts, which appears to be a more natural process (Lamon, 1996).

Partitioning involves separating an entity into equal parts. The numerator is the quantity to be divided by a particular number of parts, resulting in the value of one part. In real life situations, continuous units are cut into parts where discrete units are sorted. This is a multi stage operation that involves marking objects, cutting them and clearly indicating one person's share (Lamon, 1996). Lamon (1996) points out that students have to use more sophisticated unitizing processes when working with composite units. She claims that it is important to understand children's models of unitizing and partitioning and how they develop so that instructional decisions can serve to facilitate students' construction of increasingly abstract ideas. To this end, we provide an example of how a fifth grade student in a whole class teaching experiment solved a fair sharing problem containing a composite unit. We point out the importance of having the student symbolize their solutions while representing the problem through pictorial representations. Having students symbolize and explain their thinking forces students to think explicitly about what they are unitizing and reunitizing. The analysis

presented in this paper is part of a larger whole class fifth grade teaching experiment on children's development of the quotient construct.

### Method

A five-week whole class teaching experiment was conducted in a fifth grade classroom in an urban school district in the Southwestern United States. Nineteen students and the classroom teacher participated in the study. Two cameras video recorded the teaching episodes. One focused on the teacher and the other on a focus group of 4 students. All students written work in math journals were documented along with the whole class inscriptions. Student work and whole class inscriptions were coded and analyzed. The videotapes were transcribed. The classroom discourse was analyzed in relation to the activity of creating and translating inscriptions to make meaning of the quotient construct. The emerging hypothetical learning trajectory of the whole class was documented. A students' solution to a problem from the teaching experiment is used in this report to illustrate the unitizing process involved in solving a fair sharing problem containing a composite unit. The students were asked to solve the problem of 5 children equally sharing 6 packs of gum with 5 pieces in each pack.

### Results

Students conceptualized the unit of 6 packs of gum with 5 pieces in each pack as either packs, pieces or both as they solved the fair sharing problem containing a composite unit. Students were asked to symbolize their thinking along with their pictorial representations. Students symbolized their actions of partitioning through pictorial representations as opposed to symbolizing the number sentences. Even though students were able to figure out the correct answer and justify their reasoning, most students did not write number sentences to represent the original problem and solution. The difficulty in doing this was due to the fact that students had to explicitly think about their unitizing and reunitizing processes related to the problem context as represented in relation to their answers. For example, Karen conceptualized the problem as packs and pieces. She drew a  $5 \times 6$  matrix to represent the 30 sticks of gum (see figure 1). Each column represented a pack of gum containing 5 sticks of gum and the symbol inside the matrix represented pieces of gum in each corresponding pack. Therefore, she needed the visual aid of the discrete pieces to keep track of the packs.

She wrote the fraction  $5/5$  to represent 5 pieces of gum shared by 5 kids. This fraction represented how one pack was split among 5 kids. She treated the pack as 5 discrete pieces. Next, she indicated that  $5 \text{ (packs)} \div 5 \text{ (children)} = 1$  pack of gum. In doing so, she conceptualized the 5 packs as divided among 5 kids. Each pack was treated as a composite unit. She checked her answer using the inverse operation to check her arithmetic that  $5 \times 1 = 5$  and she indicated that the resulting 5 represented 5 pieces of gum. Karen had confused herself during the process of reunitizing by shifting her thinking from packs of gum back to pieces of gum. However, later on she caught

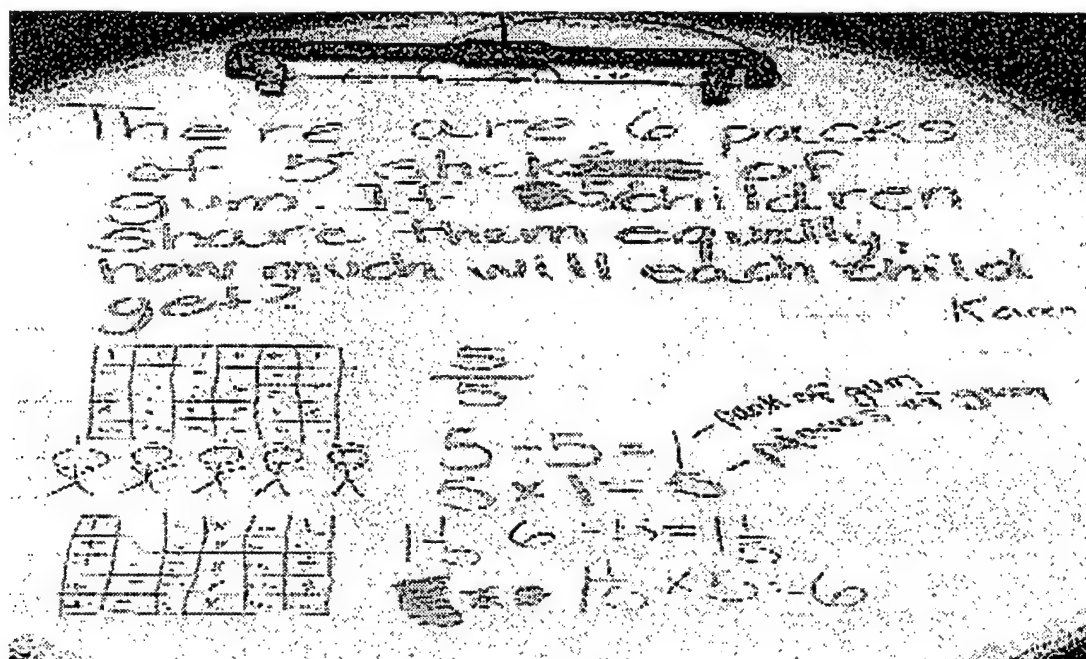

Figure 1. Karen's Method.

her error and re-explained her thinking as indicated by the matrix listed at the bottom of figure one. She concluded that each kid would get  $1 \frac{1}{5}$  packs of gum. She treated each column as representing one pack and each piece as representing one fifth of the pack. She used the Mark-all strategy as defined by Lamon (1996). Karen concluded that each child would receive one column of 5 pieces and 1 piece that represents  $1 \frac{1}{5}$  of the pack. She was thinking in packs, but used the visual support to simultaneously think about the pieces.

### Discussion

Students should have the ability to conceptualize a composite unit in a fair sharing problem situation in flexible ways such as packs and pieces in order to successfully solve the problem. The student did not have much difficulty partitioning the unit into smaller pieces, however she did get confused as she reunitized the problem into packs and pieces. This is consistent with Lamon (1996) findings that the students have easier time decomposing the units as opposed to reunitizing. Furthermore, Lamon (1996) had indicated the importance of having perceptual support specially when students use a mark all strategy as illustrated in the example provided in this paper. Having students symbolize their thinking and providing explanations of their thinking of their symbolization and visual representations appear to help students think explicitly about unitization and reunitization processes while problems solving. Furthermore, having students gain initial experiences with discrete and continuous problems prior to tackling problems that involve nested composite units might be helpful.

## **A COMPARISON OF CONTENT TREATMENT FOR THE TEACHING OF PERCENT IN SELECTED AMERICAN AND CHINESE MATHEMATICS TEXTBOOKS**

Yeping Li

University of New Hampshire

yeping@math.unh.edu

This study examined selected American and Chinese mathematics textbooks in terms of their ways of presenting and organizing content for the teaching and learning of percent. The results provide a glimpse of different metaphors of mathematics learning that have been employed in American and Chinese textbooks. In particular, much more differences than similarities are found between the selected textbooks in what students need to learn and how to facilitate their learning. Further studies are needed in near future to include more textbooks and more content topics.

Efforts to identify contributing factors for cross-national differences in students' mathematics achievement have led to the contention that the curriculum is one of the key factors (Lapointe, Mead, Askew, 1992; McKnight, Crosswhite, Dossey, Kifer, Swafford, Travers et al., 1987). Large-scale international comparisons of students' mathematical achievement have provided broad measures of the differences and similarities in mathematics curricula but not a fine-grained analysis of mathematics textbooks. Mayer, Sims, & Tajika (1995) revealed the pivotal role of textbooks for teaching mathematics in their cross-national study on mathematical content presentation in texts. Other cross-national studies on mathematics textbooks (e.g., Fuson, Stigler, & Bartsch, 1988; Li, 2000; Stigler, Fuson, Ham, Kim, 1986) suggested the importance of understanding textbooks' influence on the teaching and learning of mathematics from different perspectives. In particular, studies on the selection of content topics and content treatment in textbooks (e.g., Li, 1999) show the promise of revealing different approaches that textbooks take for the teaching of mathematics. Along this line of curriculum inquiries on content, this study compared selected American and Chinese textbooks on the teaching of percent.

### **Methods**

One American mathematics textbook series and one Chinese mathematics textbook series were examined to locate the content instruction of percent in elementary school. The Chinese math textbook series (People's Publishing House, 2000) bears the approval of Chinese Ministry of Education and is the most popular one in China. The American textbook series is "Progress in Mathematics" (McDonnell, Burrows, Murphy, LeTourneau, Geschke, & Kelly, 2000). This selected American textbook series is, by no means, a representative one in the United States. The selection of this series, only as the first step, tries to illuminate possible similarities and differences between American and Chinese textbooks.

The two textbook series were examined first to locate the grade level(s) when the topic of percent is introduced. Textbook treatment of percent and other content topics in the textbooks was described. Further comparisons were then given to specify how the content topic of percent was introduced. Textbooks' uses of different representations, worked-out examples and exercise problems were also examined to show their approach for the teaching of percent.

## Results

### Textbook Placement of Percent Topic

In both American and Chinese textbook series, the content of percent is first being introduced at the fifth grade. The American textbooks take a spiral approach and introduce the topic of percent again at the sixth grade. In contrast, the Chinese textbook takes a sequential approach to introduce the topic of percent only at the fifth grade. Although both American and Chinese textbooks place the topic of percent after the content of fraction, they differ in dealing the topic of percent with ratio and proportion. In particular, Chinese textbook introduces the content of percent before ratio and proportion whereas American textbooks combine the introduction of ratio and proportion with percent as one chapter at both fifth and sixth grade levels.

### The Introduction of Percent Concept

The concept of percent is defined as "A fraction with a denominator of 100 can be written as a percent. Percent means the part of each hundred. The symbol for percent is %." in the American fifth-grade textbook, as "A percent is a ratio that compares a number to 100." in its sixth-grade textbook. In contrast, the Chinese textbook introduces the concept of percent based on the concept of fraction. It differs from the American textbook by defining the percent as "the number that represents one number as how many parts of 100 parts of another number. It can also be called percentage."

Specifically, American textbooks present the definition of percent directly and then ask students to work with 10x10 grids. For example, students are asked to shade 32 squares in a 10x10 grid or to figure out what percent of squares is shaded. In contrast, Chinese textbook presents a problem situation first: There are 17 students being evaluated as excellent in 100 fifth graders, and 30 in 200 fourth graders in an elementary school. Which grade has a higher rate of excellent students? To solve this problem, the textbook uses the concept of fraction equivalence, and leads to the definition of percent. Mathematically, the differences in their introduction of percent show that the American textbook defines the concept of percent as a fraction or ratio, whereas Chinese textbook defines the concept of percent based on the concepts of fraction and fraction equivalence.

### **The Relationships Between Percent and Fraction, Decimal**

In American texts, the relationships between percent and fraction and decimal are introduced in the fifth-grade text first, and then repeated in the sixth-grade text. Similar problem contexts and 10x10 grid are used in the texts of both grade levels. The general rules for converting percent and fraction, percent and decimal are also introduced at both grade levels. Similar to the American text, the Chinese text also introduces the conversion between percent and fraction, percent and decimal. However, the general rules of conversion are not given first. Students are prompted to generalize from several examples being given. Moreover, the conversions made in the examples are not explained with 10x10 grid, but based on the definition of percent. For example,  $0.123 = 123/1000 = 12.3/100 = 12.3\%$ .

### **The Application of Percent**

The application of percent is included in both American and Chinese textbooks, but shows quite a big difference. The American textbook presents very limited application of percent, but places much more emphasis in introducing problem-solving strategies. In contrast, the Chinese textbook places heavy emphasis on the application of percent. It includes examples of percent application in all three different cases: (1) finding the percent when the whole and part are known, (2) finding the value of whole when the percent and part are known, (3) finding the value of part when the percent and whole are known. The examples given for each case are also varied, if possible, after solution. Practice problems contain many more variations in problem context. Other applications such as “interest”, “chen (a Chinese way of using 10%)”, and “discount” are also introduced with examples and practice problems.

### **Discussions**

The study shows much differences than similarities between the selected American and Chinese mathematics textbooks on their treatment of percent. Taking together, these differences may suggest different metaphors of mathematics learning that have been employed in American and Chinese textbooks to organize and present mathematics content. Specifically, the selected American textbooks try to decrease the difficulty of math content by using spiral organization of content, direct introduction of content being taught, use of visual representations to facilitate students' learning, and include examples and exercise problems that are not mathematically challenging. In contrast, the selected Chinese textbook tries to maintain the content coherence and challenge by using a sequential organization of content, expecting students' involvement in learning from examples, emphasizing logical reasoning with concepts and problem analysis, and include examples and exercise problems that are mathematically intriguing. The differences, in general, indicate that the selected American and Chinese textbooks were developed with different assumptions about what students should learn and how

to facilitate their learning. Because of the limitation of textbook selection, however, further efforts will be needed in near future to include and analyze more textbooks.

# **Reasoning and Proof**

## EXPLORING SOCIOCULTURAL ASPECTS OF UNDERGRADUATE STUDENTS' TRANSITION TO MATHEMATICAL PROOF

Maria L. Blanton

University of Massachusetts Dartmouth  
mblanton@umassd.edu

Despina A. Stylianou

University of Massachusetts Dartmouth  
dstylianou@umassd.edu

This paper explores how undergraduate students come to understand mathematical proof and how classroom norms of argumentation evolved in support of this. We present here data from a discrete mathematics course to document the change in classroom norms over the course of one semester, as well as data illustrating how students' capacity for proof evolved in this context. In particular, we show how the instructor of the course established an expectation for explanation and justification, and how students' interactions developed in accordance to this through the semester. That is, we trace students' development from the passive acceptance of the instructor's authority to the expectation that students become contributors to the class and that they share common understandings. Finally, we explore linkages between this social aspect of development and the emergence of students' ability to reason deductively.

### Perspective

Arguments such as "proof is not a thing separable from mathematics....[but] is an essential component of doing, communicating, and recording mathematics" (Schoenfeld, 1994, p. 76) reinforce the centrality of proof in mathematical thinking. As such, one might expect proof activity to be embedded in curricula at all levels. However, mathematical proof has been disproportionately represented in school mathematics (Wu, 1996), and only a small percentage of students understand it (e.g., Chazan, 1993; Senk, 1985; Usiskin, 1987; Williams, 1980).

In response to this, reform efforts are calling for an increased focus on the learning of mathematical proof, especially at the college level (American Mathematical Association of Two-Year Colleges, 1995; Kaput & Dubinsky, 1993). The fact that students find proofs hard to understand and to write (Balacheff, 1988; Bell, 1976; Chazan, 1993; Porteous, 1986; Senk, 1985; Usiskin, 1987) stems from a variety of sources, including difficulty with the problem solving skills necessary to construct mathematical arguments (Schoenfeld, 1985), difficulty in understanding the mathematical language and symbolism associated with proof (Laborde, 1990; Leron, 1985), and difficulty with the concepts about which a proof is to be made (Tall & Vinner, 1981). In addressing these issues, recent studies have focused on cognitive issues in learning about proof, particularly the development of students' proof schemes as their capacity for justification progresses toward generality (Harel & Sowder, 1998). However, what is still needed is an understanding of the role of the social dimension in how students, particularly in undergraduate mathematics, come to know and do mathematical proof.

We situate an emphasis on the social character of proof within the broader theoretical perspective that development cannot be understood apart from the *social* context in which it occurs (Vygotsky 1934/1978, 1934/1986). Vygotsky maintained that one's development of self-regulatory thinking occurs through a process of internalizing events that originate on the social plane and involves the transformation of public discourse into private speech. This perspective underscores the importance of social factors when accounting for students' mathematical growth.

Our purpose in this study was to explore the role of the social in how undergraduate mathematics students came to know and do mathematical proof. In particular, operating from the premise that learning is a consequence of one's internalization of interactions that originate on the social plane, we considered the following questions:

- (1) How do classroom norms evolve in an undergraduate mathematics course focusing on mathematical proof?
- (2) How does mathematical proof and the language of proof come to be internalized by students in the context of existing classroom norms?

### Method

Participants for the study were a group of 50 undergraduate mathematics students enrolled in a two-semester, first-year discrete mathematics course emphasizing mathematical argumentation and proof. For this study, we focused primarily on the first semester of the course. The course was taught by one of the two investigators, while the other investigator collected data and provided technical assistance. Each class was videotaped and coding focused on the forms of explanation and justification used by students. Additionally, students were presented with a pre-, mid-, and post-assessment, all of which were analyzed to identify the generality, form and competency of students' arguments. That is, we examined transitions in students' written arguments for increasingly generalized and more formalized expression of those arguments, which we took as evidence for shifts in students' capacity for self-regulatory thinking.

### Results

While it is difficult to establish a direct link between a succession of classroom conversations and, for example, students ability to construct written arguments for proofs, we do claim that the norms established in this classroom supported the development of argumentation required for constructing mathematical proofs. We take shifts in student responses to one proof problem given on three occasions as part of the evidence for this claim.

A typical class began with a problem introduced by the instructor followed by student group work. Students were encouraged to ask each other questions and help each other clarify concepts and problem requirements. The small group work usually

alternated with whole class discussion of students' approaches, thinking and questions. Throughout the course there was a concerted focus on both written and verbal expression of student thinking. The instructor worked to establish the expectation that students explain their reasoning, try to make sense of each other's explanations, and challenge each other's reasoning and justifications. Our analysis shows that there were shifts in how students came to operate within classroom norms. As the following episode illustrates, students were initially hesitant to participate in discourse and to challenge the thinking of their peers or the instructor, and even lacked the language to do so. The class was introduced to combinations and permutations and students were asked to find the number of different combinations of pastries one can purchase from a bakery. The instructor prompted students to collaborate with a partner and to "think about their thinking" and to question each other's approaches and arguments, thus implying an expectation that students would share their reasoning. The interaction, which occurred during the third week of the semester, took place between Isabelle and Josh (pseudonyms):

1. Isabelle: What did you do?
2. Josh: You multiply them all out and you get  $10 \times 9 \times 8 \times \dots$
3. Isabelle: Oh, OK.

The level of discussion described in this short episode illustrates the discussions that took place among almost all groups. Although students were asked to collaborate in solving the problem, making sure to question each other's thinking, they instead tended to ask each other (or the instructor) for a procedure for solving the problem and accepted each other's solutions without further questioning. In the few cases where a student asked another student for further clarification or explanation for his answer or approach, the response often was "it worked for me!" At this point, it was not the norm for students to challenge each other's thinking. In fact, it seemed that another cultural norm was still at work, namely, that the goal in solving a problem was to get a solution (as quickly as possible) and that, if one would merely *describe* the procedure, then analyzing the process would be unnecessary for understanding. That is, students would be able to simply replicate their own or their peers' procedures in solving other problems. As students came to learn, however, the nature of the content was such that no single procedure worked for a broad class of problems (in the way that, for instance, techniques of differentiation allow students to solve large volumes of similar problems). Thus, it was imperative that they begin to question the process of one's thinking in order to tease apart 'techniques'. This was further supported by the instructor's routine of allowing students to work with partners in lengthy exchanges (for example, it was not uncommon to allow students 10 to 15 minutes to begin to sketch out a proof), or by the instructor removing herself from the conversational space during whole-class discussion, thereby requiring students to build cases whose

validity was argued exclusively by students. Moreover, the instructor worked to make her own process of argumentation explicit for students and to focus their thinking on anticipating the steps in an argument while keeping track of how given information could be used.

As the semester progressed, we observed that the *quality* in students' oral and written explanations and their capacity to express their mathematical thinking in increasingly formalized ways changed substantially. Students' arguments gradually shifted from empirical and procedural to deductive and conceptual. Moreover, students grew accustomed to engaging in explanations and justifications and seemed to internalize a more formal language of proof reflecting that used by the instructor during regular instruction. We take the following, which illustrates how students came to argue the simple conjecture that "the sum of an even and odd number is always odd" (Odd/Even Conjecture), as part of the evidence of our claim.

The Odd/Even Conjecture was administered as part of a larger assessment on proofs on the first day of class (before any instruction occurred), 9 weeks later, and at the final class of the semester. We note that it was administered in partner pairs for the mid-test, and while this no doubt contributed to the significant improvement, the individual post-test indicates that students had reached a comparable (slightly better) individual level of performance by the semester's end for this particular problem. Of the proofs assigned throughout the semester, this was one of the simpler problems. To interpret the results, we include here a possible solution to the conjecture.

*Odd/Even Conjecture: What happens when you add an even and odd number? Prove that your conjecture will always hold.*

*Possible solution: Let  $x$  be even and  $y$  be odd. They  $x = 2m$  and  $y = 2n + 1$ , for integers  $m$  and  $n$ . Then  $x + y = 2m + 2n + 1 = 2(m + n) + 1 = 2k + 1$ , where  $k = m + n$  is an integer. But  $2k + 1$  is odd, by definition, so  $x + y$  is odd. Thus, the sum of an even number and an odd number is always odd.*

One student (Daniel – pseudonym) wrote the following on his pre-test, a response that was fairly representative of the range of responses:

*The result will always be odd.  $1 + 2 = 3$ .  $x + x + 1$  is odd.*

He then tried to solve the equations  $2x + 1 = 3$  and  $2x + 1 = 4$ . His comments about his 'proof' were

*[I] can see intuitively that odd + even = odd. But how to prove, I don't know what to say, generically. If you solve after setting  $2x + 1 = [sic]$  to an odd number you get a whole number,  $[sic]$  to an even number you get a fraction. Hmm... Obviously need some generic method to prove. Oh well.*

At this point, Daniel does not have a formalized way to think about arbitrary even or odd numbers (i.e.,  $2x + 1$  for some integer  $x$ ), although in the expression ' $x + x + 1$ '

he does recognize that consecutive even and odd numbers are separated by a unit. Although he records this information, he does not use it to build an argument. The class proved a set of problems similar to the Odd/Even Conjecture, although they solved this particular one only on the pre-, mid-, and post-tests. Daniel's response on the post-test was much different:

*Let  $n, m$  be integers.  $2n$  is even.  $2m+1$  is odd. ( $2 \bullet$  any integer is divisible by 2 and hence even. Add 1 and it is odd.)  $2n + 2m + 1 = 2(n+m) + 1 = 2p + 1$ , where  $p$  is an integer.  $2p + 1$  is odd, so even + odd is odd.*

In this response, Daniel identifies arbitrary even and odd integers and uses this definition to symbolically argue that the sum of an even and odd is odd. While this sequence of maneuvers is not complex, he initially did not have the language (even everyday language) to build this type of argument. Following are the class results on the Odd/Even Conjecture.

These results clearly indicate significant gains in students' responses. Only one person (2%) gave either a correct or essentially correct proof on the first attempt, while 92% of the class gave correct (67%) or essentially correct (25%) proofs on the second

**Table 1.** Summary of Student Responses to the Odd/Even Conjecture

|                              | Pre-Test<br>(individual)<br>(50 responses) | Mid-Test<br>(paired)<br>(51 responses) | Post-Test<br>(individual)<br>(33 responses) |
|------------------------------|--|--|---|
| <b>Correct proofs</b>        |  |  |   |
| completely correct           | 2%   | 67%                                    | 67%   |
| almost correct (minor error) | ---  | 25%                                    | 27%   |
| Total                        | 2%   | 92%                                    | 94%   |
| <b>Incorrect proofs:</b>     |  |  |   |
| Used examples as a "proof"   | 52%  | 4%                                     | 0%  |
| Used illogical reasoning     | 20%  | 4%                                     | 6%  |
| Looked at a narrow case      | 20%  | 4%                                     | 0%  |
| No attempt made              | 14%  | 0%                                     | 0%  |
| Total incorrect proofs       | 98%  | 8%                                     | 6%  |

attempt (paired mid-test), and 94% of the class gave either a correct or essentially correct proof on the final attempt. Students whose response was scored 'almost correct' had expressed a more limited argument by using the same variable in the generalized expressions of an arbitrary even and odd number (i.e.,  $2x$  and  $2x + 1$ , rather than  $2x$  and  $2y + 1$ ). In addition, 52% of students on the first attempt used examples as their method to 'prove' the conjecture, while only 4% of students used this as a strategy on the second attempt, and no students used this as a strategy on the final attempt. Moreover, there was a significant increase in students' level of formalization, particularly, their capacity to express their thinking in increasingly formal ways via symbolic language. Only 16% of respondents on the pre-test used some form of symbolization, whether correctly or incorrectly (otherwise, if students attempted a proof, they used everyday language). Meanwhile, on 94% of the mid-tests and 97% of the post-tests students expressed their proof or proof attempts symbolically in a manner similar to the possible solution given here. We take this as evidence that students were beginning to internalize a more formal or symbolic language of proof used in instruction (that is not to say that they did not at times use symbols in illogical ways).

Students' also shifted in their conception as to what counts as a strong mathematical argument. For example, during the first weeks of class the instructor's request for explanation or proof often resulted in procedural descriptions or the listing of several examples. However, ultimately students attempted to explain the generality of their arguments. We maintain that they came to act within the norm of justifying their thinking in ways that required increasingly sophisticated notions of what constituted acceptable mathematical justification or proof. As an illustration, we include the following episode that occurred as students were trying to prove  $\sqrt{2}$  is irrational.

4. Jared: I set  $\sqrt{2} = p/q$ . Then I...
5. Daniel: What are  $p$  and  $q$ ?
6. Jared: Two integers
7. Daniel: Any integers?
8. Jared: Two integers
9. Daniel: If it's not *any* integers, then it's not true for all cases, and then someone can come up with a case where it fails and your argument is gone.
10. Mike: To me, the important thing to remember is that  $\sqrt{2}$  is written as a specific ratio, not any  $p/q$ . We are trying to show it can't be rational....

It seems here that the norm at work is the expectation among students that their peers should explain their reasoning and could freely challenge one's thinking. As Jared started sharing his thoughts, Daniel asked for further explanation regarding the

generality of Jared's use of integers. Mike joined the discussion in an attempt to clarify the argument further, which seems to be determining whether 'p' and 'q' represent a fixed but unknown pair of integers, or whether they represent any two arbitrary integers. Mike's language further suggests that the argument is a collective one. He notes that "*we* are trying to show it can't be rational" (emphasis added). It is no longer Daniel's attempt to show that the square root of 2 is irrational. It is an argument embraced by the class (or some subset thereof) as their responsibility.

We maintain that active dialogues such as this were essential for and reflective of an internalization of knowing and doing mathematical proof. Moreover, we argue that as students were increasingly able to create these conversations, it changed the structure of public discourse and allowed for a more advanced form of collective debate so that interactions such as that given by 4-10 became both tool and result of the mediated language of students. In contrast, the protocol given earlier shows no argumentation and suggests a passive interchange between students. We maintain that these structural differences in the forms of interactions among students indicate an evolution in how they thought about mathematical proof. Moreover, this shift did not occur in a vacuum or as a result of watching (passively) a teacher record steps to proofs which students were expected to mimic with similar problems. Instead, it required classroom norms that particularly supported the opportunity for public debate and scrutiny. As such, it seems that discussions such as that between Jared, Daniel, and Mike helped to build a habit of mind whereby students could internalize public argumentation in ways that could facilitate private proof construction.

Constructing a proof is ultimately a process of logical argumentation. We maintain that, for most students, this process is learned in the context of *public* argumentation that makes not only the arguments, but the thinking behind the arguments an explicit part of the conversation. It is in the context of active public debate that students learn how to question, dissect arguments, and build justification as they engage in the act of doing so. In this study, classroom norms were established in which proofs could be socially constructed and in which the components of an argument and one's reflective and anticipatory thinking about a proof were a part of the public discourse. We maintain that these supported students' emergent capacity to construct proofs as well as their internalization of an increasingly formal language for expressing their ideas. More work is needed to understand how diverse kinds of classroom norms, both social and sociomathematical, lead to different types of knowledge and understanding about proof.

## ENABLING STUDENTS TO MAKE CONNECTIONS WHILE PROVING: THE WORK OF A TEACHER CREATING A PUBLIC MEMORY

Patricio G. Herbst  
The University of Michigan  
pgherbst@umich.edu

The possibility to connect present inquiries to prior knowledge is crucial in students' ability to prove conjectures. How to organize the storing and recall of that prior knowledge is an important piece of the work of teaching. The complexities of such task are particularly revealed in the case of engaging students in making and proving conjectures in geometry. Using records from a classroom intervention in high school geometry, this article examines what are some of those complexities and what is involved in a teacher's management of such complexities.

Problems and tasks can be useful contexts for students to use mathematical reasoning to construct new knowledge (Brousseau, 1997; Lampert, 2001; NCTM, 1991, 2000). As Ball & Bass (2000) show, the possibility for reasoning to play such role in the construction of knowledge hinges on the existence of a base of public knowledge that students can use and language appropriate to formulate and represent claims and arguments. The present article takes that conversation a step forward and argues that students' access to such base of public knowledge as they engage in reasoning and proving depends on how existing knowledge is organized for public use. Furthermore, that the nature of such "public memory" can be problematic for a teacher.

Proof is a prominent tool to articulate connections between mathematical ideas: Proof plays that role not only in the producing new knowledge (Lakatos, 1976) but also in the re-presentation and organization of that knowledge inside larger theories (Rav, 1999). Proof is also prominent in NCTM's Principles and Standards for School Mathematics (*PSSM*) for similar reasons—as the document invites teachers to help students understand the crucial role that reasoning and proof play developing new knowledge from old knowledge and making connections.

But classrooms are complex environments. They are complex not only in regard to the interpersonal dynamics that may develop in the contexts where individuals come to know and use mathematics (Chazan, 2000; Voigt, 1994). Classrooms are complex environments also in regard to the positions and responsibilities that teachers and students have vis-à-vis each other and the subject matter they must teach and learn inside the schooling institution (Brousseau, 1984). There are specific complexities associated with managing the use of existing knowledge in proving new conjectures. These complexities may be especially manifest in classrooms where the subject of studies is organized in a deductive fashion and yet students' opportunities to develop new knowledge are constituted in and through their work on problems. I focus on one particular aspect of this complexity, managing the creation of *labels* for (or public records of) the new ideas that students develop and their later use in constructing

public arguments. I want to argue that such work of developing a public memory that students can use in proving may create tensions in the work of teaching.

The argument that I want to present has two parts. First, I argue that labels of shared classroom experience may play an analogous role in developing arguments for new conjectures as postulates and proven theorems play in the mathematical presentation of a new result. In that first part of the argument I suggest that the creation of conditions for students to prove new conjectures require deliberate actions on the part of the teacher. One of those deliberate actions is the sanctioning of labels for chunks of students' previous mathematical experience, labels that students may use to think with. I discuss two examples of how students' public solutions to problems were publicly recorded into labels that they could use later to make and argue for geometric conjectures that were not perceptually evident. Second, I observe that in the examples considered, those public records of experience that were used to prove new, non-evident propositions did not correspond univocally to mathematical objects that students were supposed to learn—they were in fact made up labels, meaningful only to the class that would use them. Thus, I argue that no matter how usable, the nature of those labels may confront a teacher with a problem. Some of those records and labels for mathematical ideas and experiences that students might find useful in making arguments might also be transitory items of knowledge that need not (and perhaps should not) be remembered in the long run. They may compete for attention with other, more general, items of knowledge that students must remember for future use. To keep those records in memory, though helpful for the work that students do in a particular period of their studies as they investigate a particular set of questions, might conspire against the general organization of the subject that they are supposed to study. The making of labels for experience could also make the knowledge to be learned more fragmentary, even idiosyncratic. The two parts of the argument suggest that there is a potential tension for a teacher that concerns the work that he or she might do creating a public memory. I discuss the issues at play in managing that tension, using records from a collaborative classroom teaching experiment in high school geometry—a particularly fertile context where to inquire on this problem.

### **Theoretical Framework**

#### **The Didactical Contract**

This paper contributes to the development of theory for understanding how the interactions between teacher and students about their subject of studies in classrooms shape the particular ideas and practices that students have access to. I build on Brousseau's theory of the didactical contract (Brousseau, 1984, 1997) which postulates that those interactions respond to a hypothetical contract that establishes global, mutual responsibilities for teacher and student vis-à-vis the subject matter. The teacher is responsible to teach mathematics to the student; the student is responsible to study

mathematics with the help of the teacher; the subject at play in their interactions must defensibly correspond to the discipline that they are expected to teach and learn. Teacher and students negotiate the particular ways in which those responsibilities apply for the specific tasks that they do. Those negotiations play a role in shaping the specific ideas and practices at stake in those tasks, and how teacher and students interpret the work done around those tasks in relation to the global responsibilities that they have contracted with each other.

Thus the theory recommends paying attention to the relationship between the mathematical activity constituted in and through the interactions between teacher and students in specific tasks and the roles and responsibilities that teachers and students have vis-à-vis the study of mathematics in a classroom. Structural factors (formal relationships between the positions of student and teacher inside an institution, institutional expectations on the knowledge to be taught and learned) and emergent factors (viable relationships between actual students and teacher engaging in specific, viable conceptions and forms of work) combine to shape a knowledge ecology. Some ideas or practices are more likely than others to exist and endure in a classroom; the theory seeks to give the means to explain why.

As teachers are those who might effect change in the knowledge ecology of a classroom, a crucial, broad problem within that theoretical approach is to understand what is viable for teachers to do within the conditions and constraints afforded by the global didactical contract. A growing body of research on mathematics teaching in classrooms (Ball & Bass, 2000; Chazan, 2000; Cohen, 1990; Lampert, 1985, 2001) has examined the work of teaching mathematics in terms of managing dilemmas, problems, and tensions that are endemic to practice (Ball, 1993). That language is being used here to describe the work of the teacher shaping the knowledge ecology of a classroom. Of particular interest here is the work a teacher does creating and managing the use of labels for students' experiences working on tasks and the relationship between those labels and the production of proofs for new conjectures.

### **Labels and Public Memory**

Students develop awareness and meaning for mathematical ideas through their experience in classroom tasks (Doyle, 1988). "One of the key devices human beings have for learning from experience is the use of a label to refer to elements of experience" (Mason, 1999, p. 187). What Mason calls *labels* include words, phrases, sequences of words, or slogans that may be used to refer to generic "fragments"—the building blocks for descriptions of experience. Yet labels don't just organize the storage of past experiences, they can also be oriented toward triggering the recall of experiences—in particular labels may serve action (know-to act) in context. Thus if "labels are the constituents of theories" (Mason, 1999, p. 190) that can act as "nodes in a web of connections [and] inform our actions" (p. 205) their creation, nature, and function in a classroom are of special interest. Brousseau (1997, p. 246) notes that

students' memories are not merely cognitive entities but didactical (or instructional) ones, in that teachers organize them in complex ways, to serve not only the reactivation of what is needed when it is needed but also the forgetting of what is not needed. Thus the creation or endorsement of labels for students' experience is an aspect of the work of the teacher managing what can be known, in particular what can be proved, in the classroom.

The theory of the didactical contract is particularly helpful in turning that interest on the creation of labels for activity into a problem to be studied. In terms of the global didactical contract, the roles and responsibilities between teacher, student, and subject of studies have special entailments in the case of geometry that relate to the creation and management of public labels. Among the high school mathematical subjects, geometry is not only one that has had a longstanding presence in the curriculum but is also one with evident ties to a specific mathematical domain. The objects that teachers must teach and students must learn are highly prescribed by tradition and by the discipline (a discipline whose foundations have not changed much in about a century). The subject tends to be presented and structured in accordance with the axiomatic-deductive method. In fact the teaching of geometry is often predicated on the argument that it involves students in the study of a mathematical system (Moise, 1975). Of all subjects, geometry is a special place where students have the chance to develop mathematical values such as the notion that a general proposition implicitly includes particular propositions as consequences or corollaries, and that those need not be explicitly labeled to be taken as known. And the subject is populated by many technical names for concepts and propositions that students must remember to be able to operate within. All of that to say that insofar as the structural relationships between teacher, student, and subject of studies, it is a plausible hypothesis to say that geometry imposes stringent constraints on teacher and students regarding what should and could be labeled and committed to memory. Namely, there are plenty of definitions and theorems that must be labeled and remembered in accordance with the discipline; others that are dictated by tests; those are the ones that students are accountable to study and learn. There also are substantive disciplinary reasons why some other things, propositions for example, should not be labeled and committed to memory. If those propositions were particular instances of known theorems, they could suggest tasks that teachers could use to gauge students' ability to move from the general to the particular.

Yet the teaching and learning of specific geometric ideas occurs in and through engagement in particular activities. To the extent that an activity may have been chosen to mediate the teaching and learning of an idea, securing students' engagement in that activity is a way for the teacher to fulfill what the didactical contract requires of him or her. But fostering that engagement or, more generally, making those activities viable, requires specific negotiations between teacher and student, negotiations that specify a context for the development of the new idea and thus affect its meaning.

The negotiations undertaken to make an activity viable may include a variety of things (e.g., undertaking a simpler activity first, legitimating certain forms of participation, or changing the stakes). Negotiations can be accomplished interactively (as in bargaining the price of an automobile), or they may result from unilateral moves (as when setting goals for a fundraising campaign upon analysis of donors' likely behavior). The creation of labels for previous experiences is another possible outcome that may proceed from (either kind of) negotiation and be oriented toward making an activity viable. This is particularly interesting to examine when the activity includes the expectation that students come up with a conjecture and provide a proof in a place like the geometry class. Indeed proof activities in geometry customarily require the justification of the steps of an argument by reference to labels (for theorems and concepts). It is therefore quite plausible that students' capacity to develop a proof for a conjecture hinge on having labels available to be used in justifying their arguments and hence, that the teacher's disposition toward endorsing a label responds to the need of making the proving activity viable.

The foregoing discussion thus permits to anticipate that enabling students to connect new knowledge to existing knowledge through proving might require the use of labels that identify experiences in the public memory. Those labels might or might not necessarily belong in the knowledge to be studied. Thus the theoretical approach sketched above permits to anticipate that in managing the constitution of a public memory useful to enable students' proving, a teacher must ponder two kinds of considerations. Considerations of what elements are useful to keep in memory in order to make the work possible need to be balanced with considerations of what elements must be kept in memory in order for the work done to comply with the global responsibilities imposed by the didactical contract. In the sequel I illustrate how these issues played out in the teaching and learning of area of plane figures in a high school geometry class. I report on the work of a particular teacher enabling her students to connect new knowledge through proving by endorsing labels that were not part of the subject of studies.

### **A Collaborative Classroom Teaching Experiment on Area of Plane Figures**

I worked collaboratively with Megan, an experienced high school geometry teacher to design and teach a three-week replacement unit on area of plane figures. The unit (called "Speaking the truth about area without calculating areas") was structured as a series of problems and questions where students would have the opportunity to conjecture and prove key properties of area. It started from acknowledging what students knew about how to calculate the area for a triangle and intended to use that knowledge to develop the formulas for area of other plane figures. Further, the unit was designed so as to give students a chance to use the formulas to make and prove claims about area relationships, modeling geometric problems algebraically, and connecting them to mathematical ideas they had studied before (such as ratio, similar-

ity, and the medians of a triangle). I refer here to two of the problems that students investigated. One was to construct a point inside a triangle so that the three triangles it determines when connected to the vertices are of equal area. The second was to find the ratio between the area of a given quadrilateral and that of its midpoint quadrilateral (the one whose vertices are the midpoints of the sides of the given quadrilateral).

The unit was implemented in three simultaneous classes taken mostly by sophomores. Megan taught most lessons for two of those classes with the help of Norah, a student teacher that collaborated with us in the project; Norah took care of teaching most lessons for the remaining class; I taught the lesson on the midpoint quadrilateral in all three classes. Data collected included conversations about design and planning, videotaped lessons, students' interviews and written work, teachers' journals, and frequent interviews to Megan or to both teachers during the time we implemented the unit as well as later on in the year and during the following summer.

The two sample problems mentioned above (splitting a triangle into three equal-area triangles and finding the area of the midpoint quadrilateral) turned out to be important highlights of the three-week experience. While working collectively in those problems students were able to produce proofs for two propositions about area that are not perceptually evident. The production of those proofs was made possible through ways of referring to existing knowledge that are central to the present discussion on the constitution of public memory. I describe briefly how labels were used in producing those proofs and then discuss how that use brings up issues regarding the work of teaching.

### Two Conjectures and Their Proofs

In the second day of the three-week unit, students were presented with the problem of finding a point inside a triangle so that when connected with the vertices, the triangle would be split into three equal area triangles. By the end of the third day all three classes had arrived at the conjecture that such point would be the intersection of the medians;<sup>1</sup> in two of those classes students had come to the board and given a proof of that conjecture. In all three classes students were given a chance to understand the general problem first. But then, as an intermediate step they had been asked to work on a simpler problem, to find a point inside a triangle and connect it to the vertices so that at least two of the three triangles thereby constructed would be of equal area. In all three classes (though not equally fast in all of them) students found that if they considered one of the medians of the triangle, and picked a point on that median, such point connected with the three vertices would create two triangles of equal area. Students were asked to justify their solutions and they did so by noticing, in diagrams like that of Figure 1a, that if  $AM$  is the median of  $ABC$  and  $O$  is on  $AM$ , then  $OM$  is also the median of  $BOC$ . Thus not only  $BAM$  and  $CAM$  are equal in area but also  $BOM$  and  $COM$  are equal in area, and hence subtracting  $BOM$  from  $BAM$  and  $COM$  from  $CAM$ , yields that two of the triangles determined by  $O$ ,  $ABO$  and  $ACO$  should be equal in area.

Figure 1a. Using “the median rule” to find two triangles of equal area.

Figure 1b. Using “the sliding triangle” to cover the area of the midpoint quadrilateral.

Two of the classes arrived at that argument by the end of the first day working on the problem, whereas the third class did so during the second day. By then many students also thought the point that would yield three equal-area triangles was the intersection of the medians. On the second day of working on the problem, students in the two morning classes had realized that the argument used to construct a solution to the simpler problem could be used to justify why the intersection of two medians would split the triangle into three equal areas. One of those students, whom I call Connor, provided a proof at the board. When Connor gave his proof that the centroid of a triangle splits the triangle into three equal areas, he used the label “the median rule” to justify four of the steps in his proof. His proof included running twice through an argument like the one sketched above for the solution of the simpler problem, to establish that if  $O$  were the centroid,  $AOB$  and  $AOC$  would be equal in area and also  $BOC$  and  $AOC$  would be equal in area.

On the last day of work on this three-week unit on area, I took charge of presenting students with the midpoint quadrilateral problem. We gave each student a sheet with a quadrilateral drawn on it (different students had different quadrilaterals) and asked them to find the midpoints of their sides, join them to form a new convex quadrilateral, and estimate the ratio between the areas of the midpoint and the original quadrilaterals. Some students folded in the corners trying to tile the midpoint quadrilateral (see Figure 1b). Many of them suspected that, even though these corners would as a rule not tile the midpoint quadrilateral, their aggregated area was about the same as the area of the midpoint quadrilateral. They also started to notice that everybody in the room had a midpoint quadrilateral that was a parallelogram. We asked them to consider a simpler problem—if the original quadrilateral were a rhombus, what could you say about the relationship between the areas? Many students in the second period class observed that

folding in the corners would in that case tile the midpoint quadrilateral without overlaps, and some suspected the fact might have to do with the diagonals of the rhombus being perpendicular (hence one of them parallel to the corner fold). Prompted to think about whether the folding argument could be made to work in the more general case, they first realized that all four vertices were reflected at different points (unlike in the rhombus case where they all would land at the intersection of the diagonals). Yet they also realized that all four vertices would always be reflected on a diagonal and that the challenge really was to make all four points coincide. Two students, whom I call Dan and Saul, collaborated in articulating for the whole class an argument. They said that if after folding vertex  $B$  onto  $B'$  one would slide  $B'$  along the diagonal  $AC$  (say, making it coincide with the intersection of the diagonals,  $X$ ) the area of the triangle should not change. They justified that assertion, and other similar ones they had to make as they proved that the area of the original quadrilateral was double the area of the midpoint quadrilateral, on “the sliding area triangle.”

### Surprising Accomplishments and the Role of Labels

The descriptions of the development of those two conjectures and their proofs are evidently too synthetic. The point in reporting them here is to note that students in these classes were able to do things that many, themselves and their teachers included, would judge surprising: Finding out and justifying the solutions of two non trivial problems, by drawing deductive connections to what they knew about area. The descriptions above also draw attention to the role played by two labels—“median rule” and “sliding area triangle”—in making those proofs possible. I now discuss what those labels meant and how they were instrumental in helping students construct these arguments.

Partly in response to Megan’s doubts that students would be able to figure out the triangle splitting problem, the work planned for the first day of the unit had included asking students to split triangles into two triangles whose areas stood in a given ratio. In the context of splitting a triangle into two whose areas were in a 1:1 ratio, students had been reminded that they already knew the name for the segment they had drawn to do the splitting—they knew it as the *median*. And they had been asked to prove that two such triangles were indeed equal in area—which they did by noticing that if one calculated their areas they would come out equal as both had same height and equal bases. Upon suggestion of one student, Megan had labeled that observation, that if one wants to splits a triangle into two equal areas one draws the median, “the median rule.”

The “sliding triangle” label had appeared first in the context of discussing the problems for the unit; in the context of discussing what would students have the opportunity to learn if they had to work out the “division of the land” problem.<sup>2</sup> As the design of the unit took shape, various problems were selected for students to develop awareness that triangles that share a side and whose opposite vertex lie on a parallel to

that side necessarily have the same area. In some of those problems students had had to use that observation proactively—to choose a triangle that had the same area as a given one but that satisfied an additional constraint.

From a perspective centered in the textual presentation of mathematics, both items of knowledge referred as “the median rule” and the “sliding triangle” are immediate corollaries of the triangle area formula. They are particular cases, packed inside the formula so to speak; they don’t ordinarily occupy a prominent place in the geometry curriculum. Yet, from the perspective of delivering intelligence that might inform action, those two labels are not contained in the triangle area formula—they evoke connections between situations that, I argue, were instrumental in enabling students to produce the two proofs described above. They were available not only as justifications for the arguments that students made, but also as building blocks for finding out how each conjecture could be argued. The label “sliding area triangle,” for example, did something to mediate a difficult connection—it triggered in students a way of creating and recognizing classes of equal-area triangles that was relevant in making the rhombus solution work for the general case. Similarly, the label “the median rule,” evoked for students a way of getting two triangles of equal-area, this was part of what was called for in the simpler version of the triangle splitting problem. To the extent that proving a proposition involves not just justifying statements but also strategically finding out what statements will make for a cogent argument (Greeno, 1980), these labels contained proactive elements that students could use in building up the proofs they came up with. Yet, to say that proactive labels like these are useful in enabling students to make deductive connections is only half of the story.

### **Tensions that Endorsing Labels for Experience Present for a Teacher**

The two cases observed show that students’ investment in proving important propositions was particularly enabled by the availability of labels that they could use to refer to their experiences connecting the triangle area formula with particular situations and problems where it applied. These labels triggered ways of acting that were instrumental for students in thinking about the elements of the arguments they had to construct. To enable students to make those connections as they elaborated their arguments, Megan had had to make room in her class for students to work on tasks that built awareness of those consequences of the triangle area formula. But that was not all. In addition to having students work in those tasks she had to endorse the labels—the median rule, the sliding triangle—as mathematical, as components of the subject of studies. Beyond naming experiences, labels were of particular significance, as Megan herself recognized, in enabling students to develop proofs. Students not only could recognize resemblance between situations, say between the folded corners in the midpoint quadrilateral and the division of the land problem. They also had an official name, sliding triangle theorem, they could plug in as “reason” in a proof, to justify the statement that two triangles would be of equal area. As Megan noted, having labeled

those experiences with earlier problems meant for students that “[they were] gonna use it later.”

Whereas Megan eventually had no personal objection to endorsing those labels, deciding that building awareness of those ideas was worthwhile spending time on was not immediate. Not only those tasks and problems themselves implied a detour from the tasks and problems usually included in the chapter on area, the insights about area of plane figures that they pointed to were not mainstream ideas of the curriculum either. To the extent that labels such as “sliding triangle” were evidently made up by ourselves in planning the unit, was it legitimate to include experiences geared toward students’ learning of something that needed a made-up label to be identified? Was it worthwhile to give a label to something that eventually was merely an application of the triangle area formula? Part of the justification that indeed it was worthwhile came right on the third lesson, as students were able to do something uncommon in geometry classes—to prove that those three seemingly distinct triangles split by the centroid were actually equal in area. But precisely, given that reasons in proofs are supposed to be theorems, definitions, or postulates, wasn’t it problematic to let students justify statements on something like “the median rule”? Furthermore, given that there are so many terms, definitions, and theorems that students are asked to remember in a course such as geometry, was it fair to clutter students’ memory even more? The impression that students were indeed doing surprising things helped Megan decide that it had been worthwhile to spend time developing awareness for the ideas that those labels pointed to. But the questions posed were still recognized as legitimate. If their impact was not more noticeable, it may be because the chapter on area in the text that Megan regularly uses is structured more around providing practice with formulas than around proving area properties. Similar creation and use of labels in a chapter more structured around postulates and theorems might have been more problematic for her to manage.

The discussion of the use of “the median rule” and “the sliding triangle” in Megan’s classes helps bring to the fore a foreseeable tension that a teacher may need to manage in relation to the development of a usable public memory. This tension operates in particular when the development of new knowledge is done in and through students’ engagement in problems and tasks and yet the knowledge students’ have to acquire is an axiomatized, hierarchical body of knowledge, such as Euclidean geometry. This tension may be observed as a teacher engages students in proving propositions that build on prior knowledge developed through students’ work on tasks. The tension is by no means presented here as a recommendation to avoid the use of labels in proving, rather as a construct that may help classroom observers understand what is at play in teachers’ management of that use of labels. I state that tension in more general terms.

Students experiences working on problems and tasks may help them become aware of how certain mathematical ideas can inform their actions. For a teacher to endorse labels that trigger that proactive knowledge may be instrumental in enabling

students' to construct arguments for new conjectures. Yet to the extent that such labels are more evocative of action than subordinated to deductive structure and generality, building a public memory based on those labels may conflict with expectations about the deductive organization of the subject of studies. Labels that enhance chances to produce an argument may also discourage search for the minimal conditions needed for those conjectures to be true, hence conspire against the development of mathematical theories. There is thus an opposition between the short-term availability of knowledge-to act and long-term organization of general knowledge. To the extent that a teacher is responsible for students' mastering a deductively organized subject and for their successful participation in daily tasks, managing that opposition may be difficult. Successful management may require engaging students in mediating tasks where they confront various ways of organizing the public memory.

### Notes

<sup>1</sup>Intermediate problems were posed that aimed at raising the issue of whether that solution was unique. In Herbst (2002) I have reported on some tensions that teachers had to cope in presenting those problems. Students never questioned that medians intersect at a point—they had studied (though not proved) that in the chapter on triangles some months before.

<sup>2</sup>In that problem (seen in the videos of Japanese classrooms collected by TIMSS; see Stigler & Hiebert, 1999) students are told that the fence between two neighbors is a crooked line (composed of two segments) and asked to find a single segment that will divide the lands without altering the area.

This paper presents preliminary results from the first year of a multi-year research project<sup>1</sup> exploring the development of middle school students' competencies in justifying and proving and the conditions and pedagogy necessary to promote that development. In particular, in this paper we present and discuss results from a written assessment completed by approximately 350 6<sup>th</sup> through 8<sup>th</sup> grade students. The assessment focused on students' abilities to both evaluate and generate mathematical arguments, their understanding of various aspects of deduction, and their understanding of the nature of proof. Consistent with previous results, students demonstrated an overwhelming reliance on the use examples as a means of demonstrating and/or verifying the truth of a statement. The results also suggest that there are differences among students (by grade level) with regard to their understanding of various aspects of the deductive process.

Many consider proof to be central to the discipline of mathematics and the practice of mathematicians. Yet surprisingly, the role of proof in school mathematics has traditionally been peripheral at best, usually limited to the domain of high school geometry. According to Wu (1996), however, the scarcity of proof in school mathematics is a misrepresentation of the nature of proof in mathematics: "Even as anomalies in education go, this is certainly more anomalous than others inasmuch as it presents a totally falsified picture of mathematics itself" (p. 228). Similarly, Schoenfeld (1994) claimed that "proof is not a thing separable from mathematics, as it appears to be in our curricula; it is an essential component of doing, communicating, and recording mathematics. And I believe it can be embedded in our curricula, at all levels" (p. 76). Sowder and Harel (1998) also argued against limiting students' experiences with proof to geometry, but more from an educational rather than mathematical perspective: "It seems clear that to delay exposure to reason-giving until the secondary-school geometry course and to expect at that point an instant appreciation for the more sophisticated mathematical justifications is an unreasonable expectation" (p. 674).

Reflecting an awareness of such criticism, as well as embracing the important role of proof in mathematical practice, recent reform efforts are calling for substantial changes in school mathematics with respect to proof. In contrast to the status of proof in the previous national standards document (National Council of Teachers of

Mathematics [NCTM], 1989), its position has been significantly elevated in the most recent document (NCTM, 2000). In fact, not only has proof been upgraded to an actual standard in this latter document, but it has also received a much more prominent role throughout the *entire* school mathematics curriculum and is expected to be a part of the mathematics education of *all* students. More specifically, the *Principles and Standards for School Mathematics* (NCTM, 2000) recommends that the mathematics education of pre-kindergarten through grade 12 students enable all students “to recognize reasoning and proof as fundamental aspects of mathematics, make and investigate mathematical conjectures, develop and evaluate mathematical arguments and proofs, and select and use various types of reasoning and methods of proof” (p. 56).

These recommendations, however, pose serious challenges for school mathematics students given that many students have, traditionally, found the study of proof difficult. In fact, research has painted a bleak picture of students’ competencies in justifying and proving (e.g., Bell, 1976; Chazan, 1993; Healy & Hoyles, 2000; Porteous, 1990; Senk, 1985; Usiskin, 1987). Although such research has made significant contributions to our understanding of students’ competencies in justifying and proving, such research also has its limitations. As a collective, the studies do not provide a coherent picture of students’ competencies over typical grade spans (e.g., middle school, high school), since each study was framed differently, studied different student populations in different school contexts, and relied on different instrumentation and methodology. Thus the goal of this session is to present and discuss results concerning the range of middle grade (6<sup>th</sup> - 8<sup>th</sup>) students’ understandings of justification and proof—in short, to provide a map of the conceptual terrain of middle school students’ competencies in justifying and proving.

### **Theoretical Perspective**

Researchers have hypothesized that the development of students’ competencies in justifying and proving might follow a developmental progression; that is, students’ understandings of mathematical justification are “likely to proceed from inductive toward deductive and toward greater generality” (Simon & Blume, 1996, p. 9). Waring (2000), building upon the work of other researchers (e.g., Balacheff, 1991; Bell, 1976; Fischbein, 1982; van Dormolen, 1977), proposed six levels of proof concept development:

- Level 0:* Students are ignorant of the need for, or existence of, proof.
- Level 1:* Students are aware of the notion of proof, but consider checking a few cases as sufficient (i.e., Balacheff’s naive empiricism).
- Level 2:* Students are aware that checking a few cases is not sufficient, but are satisfied that either i) checking extreme cases (i.e., Balacheff’s crucial experiment) or random cases is proof, or ii) use of a generic example forms a proof for a class of objects (i.e., Balacheff’s generic example).

*Level 3:* Students are aware of the need for a general argument, but are unable to produce such arguments themselves; however, they are likely to be able to understand the generation of such an argument (for example, by a classmate). This also includes the ability to follow a short chain of deductive reasoning.

*Level 4:* Students are aware of the need for a general argument, are able to understand the generation of such an argument, and are able to produce such arguments themselves in a limited number of (familiar) contexts.

*Level 5:* Students are aware of the need for a general argument, are able to understand the generation of such an argument (including more formal arguments), and are able to produce such arguments themselves in a variety of contexts (both familiar and unfamiliar).

This framework provided a lens for interpreting our assessment data; however, our analysis of the assessment data also resulted in further delineation of the framework. As proposed, Waring's (2000) framework focuses primarily on students' judgments of proof and approaches to proving; our revision includes further elaboration of Level 3. In particular, we have extended Level 3 to include students' understandings of various concepts (e.g., definitions, necessary and sufficient conditions) viewed as prerequisite to being able to understand and produce deductive arguments.

### Methods

Approximately 350 middle school (6<sup>th</sup> - 8<sup>th</sup> grade) students participated in this study. These students responded to a written assessment designed to measure their competencies in justifying and proving. In all, students responded to fifteen different items during a 45 minute class period; using matrix sampling, each individual student responded to eight of the fifteen items. The assessment items required students to evaluate various arguments (cf. Healy & Hoyles, 2000), generate their own arguments (e.g., Show that the sum of any two consecutive whole numbers is always odd.), demonstrate understanding of implication rules and deduction (e.g., Given the statement: If two even numbers are multiplied, then their product is even. Decide if the following statement is true or false and explain why: 286 is even, so it is the product of two even numbers.), apply definitions (e.g., Given a definition of a quadrilateral, determine whether a particular figure is an example of a quadrilateral), and discuss the nature of proof (e.g., What does it mean to prove something in mathematics?). In several cases, the assessment items were adapted from prior research studies. Data analyses were informed primarily by the theoretical perspective described above.

### Results

Due to limitations of page length, results are presented from a subset of items (full results will be presented during the conference session). Representative excerpts from students' written responses are provided to illustrate particular findings.

### Producing Mathematical Arguments

Consistent with previous research, students demonstrated an overwhelming reliance on the use examples as a means of demonstrating and/or verifying the truth of a statement (Level 1/Level 2). Further, students did not indicate in their responses any recognition of the limitation of empirical evidence as a means for establishing the truth of a statement. As an example, 70% of the student responses to the two assessment items that required them to construct an argument justifying the truth of a given statement were based on the use of examples. The following are the two aforementioned assessment items: (1) *The sum of two consecutive numbers is always an odd number. For example,  $5+6=11$  and  $8+9=17$ . Show that the sum of any two consecutive numbers is always an odd number;* and (2) *Show that when you add any two even numbers, your answer is always even. Provide an explanation that would convince a classmate that the answer is always even.*

On the one hand, the majority of these students appear to believe that providing one or more unsystematically selected examples is sufficient to prove a statement (Level 1). The following is a representative justification to Item 2: "I would take 5 different [pairs of] even numbers and then answer them [i.e., find the sum] and if she/he does not believe me, I will keep on doing it." In this case, the student seems to suggest that any five examples provide sufficient proof that the statement is always true and, if this justification fails to convince a classmate, then the selection of more examples should suffice to provide the necessary evidence to change the classmate's mind. On the other hand, a smaller percentage of these students strategically selected different types of numbers (e.g., very large/small numbers) in their efforts to produce a convincing argument (Level 2). For example, one student responded to Item 2 by selecting five pairs of even numbers: three pairs of small even numbers, one pair with one small and one large even number, and one pair of two large even numbers (including one over 100 million). In this case, the student employs a variety of numbers and combinations to show that the statement is true for different classes of numbers, including "very large" numbers. Responses of this nature suggest a certain level of sensitivity to the need to provide evidence that the statement is true, regardless of the size of the number.

A minority of students attempted to produce more general arguments for the two assessment items, with varying degrees of success. As an example, one student responding to Item 1 wrote: "Consecutive numbers are *always* one odd and one even number no matter whether I started with one even or one odd. Sums of an even number and an odd number are always odd." In this case, the student uses a feature of consecutive integers and then proceeds to utilize a mathematical declaration ("Sums of an even number and an odd number are always odd.") of his own in presenting an argument that the initial proposition is true. Although the student has attempted to present a general argument, acceptance of his argument as proof is dependent upon

the acceptance of his mathematical declaration as true (to an extent, his argument is somewhat circular).

### Students' Application of Definitions

On items in which students had to apply a mathematical definition, younger students had a tendency to use information external to that provided in the definition and, as a consequence, the use of such information often interfered with their interpretation of and ability to correctly respond to the assessment item. In other words, there seems to be a tendency, especially strong among younger students, to bring intuitive and familiar notions of a concept to bear in applying a definition; this tendency, however, appears to abate as students progress further in middle school. As an example, one assessment item required students to consider an unconventional, but technically correct, interpretation of the following definition of a quadrilateral: *A quadrilateral is what you get if you take four points A, B, C, and D and join them with four straight lines.* The "unconventional, but technically correct, interpretation" of the definition consisted of a figure with two of its four sides formed by connecting non-consecutive vertices (produced by a hypothetical middle school student named Carla). The students were then asked if this figure was a quadrilateral according to the stated definition.

In Grade 6, about two-thirds of the responses referred to a more generic definition of quadrilateral, whereas in Grade 8, about two-thirds of the responses used the specific definition provided to decide if the figure was indeed a quadrilateral. In the former case, the following is a typical 6<sup>th</sup> grade student response, one that appeals to a more generic definition: "No, it is not a quadrilateral because the sides cross." It seems clear that the student is referring to his or her own definition of a quadrilateral rather than to the specific definition provided with the assessment item. In the latter case, the following is a typical 8<sup>th</sup> grade student response: "According to the definition, Carla has drawn a quadrilateral. In the definition, it says you find any 4 points and connect them with straight lines, not in what order you have to connect them."

### Understanding Conditional Statements

The data suggest that students are far more likely to correctly interpret the conditional nature of a mathematical statement if they could readily visualize a counter-example. For example, students responded to an item consisting of two conditional statements of the form "If (A and B), then C." More specifically, students were asked to state whether each of the following statements were true or false and to explain their choice: (a) *A quadrilateral that has four equal sides must be a square*, and (b) *A quadrilateral that has four right angles must be a square*. In (a), it was apparent that, at all grade levels, the students' lack of knowledge (or recall) regarding the existence of rhombi interfered with their ability to generate a counter-example and, thus, their ability to correctly respond to the question. Interestingly, this lack of knowledge (or recall) was also evident in (b), however, more so with the 6<sup>th</sup> grade students than the 8<sup>th</sup> grade

students (statistically significant,  $p < 0.05$ ), that is, more 6<sup>th</sup> grade students responded incorrectly than did 8<sup>th</sup> grade students. Apparently, the 8<sup>th</sup> grade students had a greater familiarity with the properties of rectangles than did the 6<sup>th</sup> grade students—the 6<sup>th</sup> grade students may not have viewed a square as a special case of rectangle—and as a consequence, the 8<sup>th</sup> grade students were better able to generate a counter-example. This result may be a curricular effect in that 6<sup>th</sup> grade students may not have yet learned to classify quadrilaterals.

### Concluding Remarks

Previous research has suggested that many teachers have inadequate conceptions of proof (e.g., Harel & Sowder, 1998; Jones, 1997; Knuth, in press; Martin & Harel, 1989) and that they have limited views regarding the nature and role of proof in school mathematics (Knuth, 2002). Consequently, engaging teachers in discussions focused on the details of students' competencies in justifying and proving may provide a basis for enhancing both teachers' own understandings of proof and their perspectives regarding proof in school mathematics. In addition, such detail on student reasoning may also provide a basis for continued growth and development of teachers' understandings of their students' reasoning and, consequently, their abilities to support the development of their students' mathematical reasoning (cf. Carpenter & Fennema, 1992; Carpenter, Fennema, & Franke, 1996).

This paper on classroom factors influencing students' proof construction ability reports findings from the data collected in the first two years of a three-year National Science Foundation-funded project<sup>1</sup>. Four different classrooms, two from each participating school, were involved in the project. Data sources included videotaped classroom episodes, interviews with the participating teachers and with focus students from each class, as well as students' responses to items on the *Proof Construction Assessment* instrument. Student ability to construct proof was interpreted in the context of the classroom microculture (Cobb & Yackel, 1996). The results show that students performed poorly on items that required them to write a formal proof with no support. They also had difficulty on items that required students to make a single deduction from a given piece of information.

### Objectives

Although proof and reasoning are seen as fundamental components of learning mathematics, research shows that many students continue to struggle with geometric proofs (Chazan, 1993; Harel & Sowder, 1998; Hoyles, 1997). In order to relate students' understanding of geometric proof to pedagogical methods and other classroom experiences, our three-year project investigates two components of student understanding of proof, namely, students' beliefs about what constitutes a proof and students' proof-construction ability.

In this paper we focus on students' proof-construction ability. We summarize findings from our second year of data collection that connect student ability to construct proof in geometry to classroom factors that may influence that ability. More specifically, we address two objectives:

1. To characterize the psychological aspects of students' evolving proof-construction ability in proof-based geometry classes in order to update and expand existing research in this area;
2. To link students' geometric proof-construction ability to aspects of the classroom microculture as well as to teachers' pedagogical choices.

### **Perspectives and Theoretical Framework**

Existing research documents students' poor performance on proof items and identifies common, fundamental misunderstandings about the nature of proof and generalization in a number of mathematical content areas (Chazan, 1993; Hart, 1994; Martin & Harel, 1989; Senk, 1985). In particular, Senk's seminal study has set the benchmark for high school students' performance on geometry proofs. Other researchers (Balacheff, 1991; Harel & Sowder, 1998) have proposed frameworks that describe increasingly sophisticated strategies used by students to construct proofs. At the least sophisticated level, students appeal to external authorities for mathematical justification. At the next stage, students base their justifications on empirical evidence. Finally, students are able to use more abstract and mathematically appropriate techniques when proving statements. We have used the existing research to help us identify student misunderstandings and to characterize their strategies for constructing proofs.

The theoretical lens through which we view the classroom activities and students' mathematical development as participants in the community of the classroom is associated with the emergent perspective as described by Cobb and Yackel (1996). This perspective is useful in that it attempts to describe individual learning in the social context of the classroom. Thus student understanding of proofs (their beliefs about proofs and their ability to construct proofs) is seen as constructed on both a social level and a psychological level. In other words, the students' interactions with the teacher and peers lead to the development of taken-as-shared knowledge, or an understanding of social and sociomathematical norms. These interactions also influence individual students' developing understanding of proof. Our research focuses on individual student performance as well as the classroom microculture and teachers' pedagogical choices. By classroom microculture, we refer to social and sociomathematical norms, as well as classroom mathematical practices as defined by Cobb and Yackel (1996). We define pedagogical choices to include the choice of mathematical tasks, the ways the teacher allocates time for activities, the instructional strategies (direct instruction, cooperative learning, investigations), and the teacher's expectations about student ability that may be reflected in choices.

### **Methods of Inquiry and Data Sources**

During the two years of the project, we captured the nature of proof instruction, as well as classroom interactions and student activities, through daily observations, video recordings, and written observer field notes. This allowed us to characterize the four participating teachers and their proof-based geometry classes. An initial pair of teachers participated for two years (Mrs. A and Mrs. B). A second pair of teachers participated for only the second year (Mrs. C and Mr. D). The multiple sources of data provided information about the context for the development of proof-construction ability in order to interpret this information and connect it to the classroom norms and mathematical practices.

Student proof construction ability was determined using three types of data collected during the two project years. First, we designed and administered a performance assessment instrument to measure students' varying levels of ability to engage in formal logical reasoning. This *Proof Construction Assessment* instrument includes items in which students must construct partial or entire proofs, as well as generate conditional statements and local deductions. In addition to some original items, the instrument included items modified from Healy and Hoyles (1998), Senk (1985) and from the Third International Mathematics and Science Study (TIMSS) (1995). Second, data was collected during classroom observations, including video recordings, field notes, and student written work. Third, selected focus students participated in clinical interviews with researchers. The video-recorded interviews focused on some aspects of the Proof Construction Assessment and required focus students to create at least one original proof during the session.

### Results and Conclusions

Results of the Proof Construction Assessment provide information about individual student ability to construct proofs. Analysis of the videotapes and field notes illuminate aspects of the social context in which individual learning developed. In addition, we discuss how the classroom social context may have influenced the individual understanding constructed by the students.

#### Proof Construction Assessment Results

Table 1 summarizes results from the Proof Construction Assessment from year two. The table provides a brief description of each item on the assessment instrument as well as measures of student performance for all four classes ( $n=84$ ). Proof items were scored using detailed rubrics similar to those used in scoring the TIMSS (1995) and the National Assessment of Educational Progress (National Assessment Governing Board, 1994). The items were scored using rubrics of 5, 3, or 2 points, depending on the item. The table shows the average score for all participating students on each item. These average scores are also reported as percentages of available points, to facilitate comparison of student performance among items scored with differing numbers of available points. The last six columns display the percentage of students receiving a particular score on each item.

Item 1 on the Proof Construction Assessment required students to fill in statements or reasons in a two-column proof. The proof was a justification for "supplements of congruent angles are congruent." In general, students in all four classes did relatively well on this item. However, focus students in Mrs. C's and Mr. D's classes expressed frustration with the limitation of a pre-structured proof. Many of these students said that they would prefer to write their own proof.

Students also did relatively well on Items 3a, 3b, and 3c on the Proof Construction Assessment which required translation from an informal conjecture to a formal con-

| 6d   | Local deductions<br>(Non-parallel lines)                                  | 0.67/3<br>(22)          | 71                               | 7  | 5  | 17 |    |    |

ditional statement. The items also required the identification of “given” and “prove” statements. Students in all four classes had the most difficulty specifying all required conditions in the conditional statement. However, they had very little difficulty constructing “given” and “prove” statements that correctly corresponded to their conditional statement or to the original conjecture.

Items 6 a-d, which required students to draw a conclusion from a given set of conditions, proved to be much more difficult for all students than we expected. For these

items, students were provided with written statements describing given conditions, none of which were accompanied by diagrams. Average student performance ranged from 21% correct on part B to 63% correct on part C. Because each part only differed by the geometric content, it appeared that the combination of item type and context were influential in determining item difficulty. Students had very little difficulty concluding that a point equidistant from and between two other points was a midpoint, but had much more difficulty drawing any correct conclusion from two intersecting segments. During clinical interviews, many of the focus students noted that they were uneasy with the open nature of the local deduction items. They claimed to be much more comfortable proving a “fact,” than making one or two deductions (for which they had to provide reasons) of their own choosing.

Although all four teachers emphasized the importance of drawing a diagram and marking it with given information before beginning a proof, this approach was not found to be useful for students in solving items 6b and 6d. For example, of the 11 focus students (out of 16) who chose to draw a diagram for Item 6b, none of them provided strong conclusions (using all given conditions) with valid reasons and only two of them gave valid but weak conclusions (using only some of the given conditions) with valid reasons. In addition, for Item 6d, out of the 12 focus students who used a diagram only four of their conclusions (strong or weak) and reasons were valid. Some of the incorrect conclusions drawn by students were restatements of the given information or answers left blank. Other incorrect conclusions involved assuming additional information that was not provided (such as assuming that *intersecting* segments *bisect* each other) or carelessly choosing one conclusion from a family of conclusions, without checking for the validity of the conclusion (such as assuming that some relationship between special angles associated with parallel lines would prove that the lines were parallel). Figure 1 shows an incorrect response given by a student who did not draw a diagram. By using a diagram, the student may have been more likely to check the validity of her conclusion or reason. Another common incorrect response is shown in Figure 2. In this case, the student came to the conclusion that P was the midpoint of the line segments XY and ZW. Two of the participating teachers conjectured that the students may have assumed that the segments bisected each other, because point P was said to be between the endpoints of *segments* rather than between two points on given *lines*. Although we are not able to determine the exact cause of the misconception, it is clear that students did not attend to the precise meaning of the symbols and words that were used to specify the given conditions.

6c. Given:  $\triangle LMN$  and  $\triangle PQR$ .  $\angle L \cong \angle P$ .  $\overline{LM} \cong \overline{PQ}$ .  $\angle N \cong \angle R$ .

Conclusion: Triangle LMN is congruent to triangle PQR

Reason: Angle-side-angle postulate

Figure 1. Sample student response to item 6c.

6b. Given:  $\overline{XY}$  intersects  $\overline{ZW}$  at point P. Point P is between X and Y.  
Point P is between Z and W.

Conclusion:  $\underline{XP=PY \text{ and } ZP=PW}$

Reason:  $\underline{P \text{ is a Midpoint of } XW \text{ and } ZW}$

Figure 2. Sample student response to item 6b.

Item 5, which required students to write a multi-step synthetic proof based on given information, a diagram, and a collection of hints (essentially an outline of the proof), was less difficult for students than we expected. Although students in Mrs. C's and Mr. D's classes said that they ignored the hints (preferring, again, to do things their way), the average score for all four classes was about 70% correct. The item required students to prove that two triangles were similar that were embedded in a diagram with two pairs of parallel lines. Some of the incorrect responses included unnecessary steps, which may have taken students off-track. These students did not appear to have a sense of the direction of the proof, despite the outline provided with the hints. Some students wrote little more than the given information.

The full proofs, without hints, (Items 2 and 4) were very difficult for most students. Very few (14% and 13%, respectively) students gave fully correct responses. An additional 21% and 23%, respectively, wrote proofs that were satisfactory, containing roughly 4/5 of a correct argument. Correct responses tended to be mostly two-column proofs, but paragraph proofs were not uncommon, particularly from students of Mrs. C or Mr. D, who often used paragraph proofs in class.

For Item 2, the analytic proof, correct proofs either relied on the midpoint formula or properties of a parallelogram. Incomplete or incorrect proofs lacked justification for using the midpoint formula or lacked enough information to make a formal argument. This was particularly true in Mrs. A's and Mrs. B's classes in which students rarely encountered analytically represented figures associated with a proof. When figures were presented on a coordinate axis, it was in the context of the application of a theorem. These problems only required students to perform computations, without providing justification. During clinical interviews, students in Mrs. A's and Mrs. B's classes said they were unsure of what was required beyond the computations.

For Item 4, students were asked to show that a triangle was isosceles if the altitudes from the two base vertices were congruent (see Figure 3). Several students attempted to prove the two smaller triangles MSB and NSC congruent, although there was insufficient information to do so. Students either left out steps in their proofs, provided erroneous reasons for statements, or left reasons blank (perhaps, hoping for partial credit).

One of our focus students, Kevin who earned one out of a possible five points on Item 4, gave the following proof (copied from original script).

4. Consider the conditional statement and the accompanying diagram.  
 'If two altitudes,  $\overline{BN}$  and  $\overline{CM}$ , in  $\triangle ABC$  intersect at point  $S$  and are congruent, then  $\triangle ABC$  is isosceles.'

Write a proof of the statement.  
 Give geometric reasons for the statements in your proof.

Figure 3. Item 4 from Proof Construction Assessment.

#### Statement

1.  $BN \cong CM$  (Given)
2.  $\angle NBC \cong \angle MCB$  (Opp.  $\angle$ 's of  $\cong$  opp. seg. are  $\cong$ )
3.  $\triangle NBC \cong \triangle MCB$  (ASA)
4.  $\angle NBC + \angle MSB = \angle MCB + \angle NSC$  (Angle add.)
5.  $\angle ABC = \angle ACB$  (Substitution)
6.  $\angle ABC \cong \angle ACB$  (If  $\angle$ 's are  $=$ , then they are also  $\cong$ )
7.  $AC \cong AB$  (Opp. seg. of  $\cong \angle$ 's are  $\cong$ )
8.  $\triangle ABC$  is isos. (Def. of isos. triangle)

It can be noted that Kevin has a beginning and an end in his proof, but he writes in between does not make much sense. For example, he makes a hasty conclusion, with insufficient reasons, that triangle NBC and triangle MCB are congruent. It shows that Kevin focused on many irrelevant details and left out essential ones.

In the next section, we provide examples of teachers' pedagogical choices and describe aspects of the classroom microculture. We use this data to further explore possible connections between the social environment of the classroom and students' ability to construct proof.

### **Analysis of Teachers' Pedagogical Choices and Classroom Microculture**

As noted earlier, we conjectured that the classroom teachers' pedagogical choices would have an impact on the students as they began to construct an understanding of geometric proofs. It might be more accurate to say that the teachers' pedagogical choices influenced the classroom microculture, including students' expectations for acceptable and valid proofs, hence influencing their understanding of how to construct valid proofs.

In some ways, the four participating teachers were alike. For instance, all four teachers followed the chosen textbook quite closely for structuring daily lessons and for assigning homework. In addition, the teachers and students used very little technology (one to two days a semester for Mrs. A and Mrs. B, four to five days a semester for Mrs. C and Mr. D) and very few hands-on investigations to help students explore geometric ideas that they studied in class. All teachers allowed the students to work with partners or groups on occasion to discuss proofs or other related problems. However, one major pedagogical difference between the classes was apparent. Mrs. A and Mrs. B chose to use geometric proofs as applications of the theorems and concepts they studied in class. In other words, Mrs. A and Mrs. B would introduce a new concept or theorem, demonstrate the concept, then show how to use the concept in a proof. In fact, this often led to students learning a particular kind of proof for a particular concept. In contrast, Mrs. C and Mr. D were more likely to use proofs to introduce new concepts or theorems to students. As a result, proofs assigned by Mrs. C and Mr. D were often the basis of the next day's lesson, whereas proofs assigned by Mrs. A and Mrs. B were rote applications of proof-writing procedures with limited student autonomy in problem solving and proof writing. This may explain the poorer performance of students in Mrs. A and Mrs. B's classes on the Proof Construction Assessment. In particular, the students in these two classes had more difficulty than other students in writing unsupported proofs (Items 2 and 4). Only with the guidance of the interviewers were the focus students from Mrs. A's and Mrs. B's classes able to make progress on these items.

A sociomathematical norm that appeared to be accepted in at least three of the four classrooms was the expectation that all mathematical problems can be solved in a relatively short period of time. Teachers contributed to the perception that mathematical problems can be solved quickly by providing examples that were always provable and usually in a few steps. As a result, students developed very little perseverance, in terms of reasoning ability, and gave up quite quickly on challenging tasks. Students rarely spent very long on a particular proof. This may be the reason why some of the students' responses to the proof items without hints (items 2 and 4) on the Proof Construction Assessment tended to be brief.

To determine what the students' deemed as valid mathematical proofs, the focus students from each class were given three different proofs of the same statement that

were constructed by other students. The focus students were asked to examine and grade the proofs. Most of the focus students claimed that they were able to follow the reasoning provided although many were not able to detect mistakes in the logic of the proof. Three separate norms were revealed as students from the various classes expressed the reasoning for grading the proofs as they did. For instance, three of the four focus students from Mrs. C's class commented on the overall creativity of the proofs. They were willing to assign a higher grade to a proof they saw as creative or one that was built on an idea that they did not come up with themselves. Similarly, the focus students from Mr. D's class commented on the elegance or lack of elegance in the proofs, which is something Mr. D stressed with his students during the school year. The focus students from Mrs. A's and Mrs. B's classes appeared to be more concerned with the level of detail in the proofs. These students were less likely to consider the overall structure of the proof. Again, this seems to be in concert with the choices Mrs. A and Mrs. B made to spend class time critiquing the details of students' proofs, rather than the choice of Mrs. C and Mr. D to also reflect on the overall proof as a way of making sense of the geometric concepts involved.

A classroom practice that appeared to have an influence on students' ability to construct proofs was the taken-as-shared perception that drawing and marking a diagram was a necessary prelude to constructing a proof. All four teachers frequently reiterated the importance of this step in class by marking diagrams when they wrote out formal proofs and when they "talked through" a proof without recording statements or reasons. Diagram marking gave students an opportunity to make some progress on just about every proof. The practice of redrawing complicated diagrams, also emphasized by the teacher, was not very well followed by the students on the Proof Construction Assessment. The students who used this strategy were generally successful in the problem with overlapping triangles (Item 4, as shown in Figure 3 above).

Interviewer: Do you usually draw your own diagram or do you use the diagram given?

Aaron: Well, like if we are trying to prove overlapping triangles then I'll usually separate the triangles out, ... And then I'll also look at the one given ... so I could see the reflexive property, because if you break it apart you can't really see it. So I draw them out and I also use the diagram given.

Interviewer: So you mark things [on the diagram] as you are going through?

Aaron: Mrs. A usually tries to preach to us ... that it would probably help us to mark stuff down to like ... mark the givens and mark the ... things we see down, and write it out before we go through and start the proofs. I've caught on to that and it really helps.

A second mathematical practice that was noticed in both Mrs. A's and Mrs. B's classes was that students seem to know that they should identify the *given* and *prove* for the geometry proofs presented in their homework or other class discussions. This practice helped the students to articulate the logical beginning and the end of their written proofs. Some students who often failed to go beyond the beginning and end perceived this practice negatively. This was noted during clinical interviews when a couple of the focus students indicated that they believed their proof was valid because they knew where to start and end and they had some statements and reasons in between (which may not have been logically connected). This may be tied to the "follow-the-pattern" proof writing that was emphasized by Mrs. A and Mrs. B.

Two of the teachers (Mrs. A and Mrs. B) openly encouraged students to memorize definitions, theorems, and postulates. This became a taken-as-shared method of learning these important facts of geometry. Even so, the students in these classes often claimed to not remember the substance of the definitions, theorems and postulates and demonstrated this by incorrectly recalling the statement of the theorems when asked. For the Proof Construction Assessment, the students were provided with a list containing the definitions, theorems, and postulates as stated in their textbooks. Surprisingly, most students claimed they did not use this as a reference. The dialogue below occurred during an interview with one of the focus students from Mrs. A's class.

Susan: Cause like when she told us about Angle-Angle and all the ones that you can get with right angles, like Hypotenuse-leg, I never understood it. And I never remembered any of it...

Interviewer: Did you look at the sheet that was given that had the theorems and postulates listed?

Susan: It wasn't helpful, because I was kind of like Ok, so what does that say?

Interviewer: So as you were reading them off the sheet, that was difficult for you?

Susan: Yeah, since I didn't grasp the concept the first time when she taught it to us, it didn't really even matter that it was on the paper.

Although the other two teachers (Mrs. C and Mr. D) did not explicitly state the need for memorization of definitions and theorems, they expected the students to begin to learn these through frequent use. Students were encouraged to write out theorems in their proofs, rather than to write a title for the theorem, such as the Angle-Angle Similarity Theorem as referenced in the dialogue above. At this point in our research, it is not clear how familiarity with and understanding of theorems and definitions influence student proof writing ability. It is becoming apparent, however, that the teachers' pedagogical choices greatly influence the students' views of what constitutes a valid

proof, as shown in the discussion of the interview questions related to students grading proofs done by peers. The students' growing sense of what constitutes a valid proof appears to have played a role in the students' proof construction.

As the analysis of our rich data continues, we hope to identify more clues related to the teachers' choices and aspects of the classroom microculture that influence student understanding of proof. At this point, our findings support those of Senk (1985) who identified aspects of proof construction that were difficult for students. It was most difficult for students to write formal proofs of statements with no hints given. We are beginning to notice, however, that teachers' expectations play a key role in student proof construction ability. In particular, it appears that if teachers focus on the overall structure and need for proofs in understanding the underlying mathematical concepts, students will also develop a better sense of the need for proof. On the other hand, if teachers expect students to learn to do proofs in a more mechanistic way, the students are likely to see proofs as just another exercise or application and will not develop a more complete understanding of proofs and how to construct proofs. These findings are supported by Battista and Clements (1995) who suggest that the teaching of formal proof should follow from helping students make sense of mathematical ideas. In other words, proofs should be seen as a way to establish the validity of one's ideas. Further analysis of our data is needed to determine how the teachers' expectations influenced student ability to construct proofs.

One surprising result was the difficulty students had with the local deductions problems. Although it is not part of our current plan to investigate this further, these open-ended deduction items may be a key step in creating formal proofs. Another avenue of analysis will be to investigate the students' proof construction ability in terms of the proof schemes described by Harel and Sowder (1998). These proof schemes are defined as what the student believes to be a valid way of ascertaining truth for herself or himself as well as persuading others of the truth of a situation or observation. For those students in Mrs. A's and Mrs. B's classes, it is unlikely that they hold very strong proof schemes, since from interviews with focus students, they appear to view proofs as exercises and not necessarily a means of ascertaining truth.

# CONSTRUCTING MATHEMATICAL ARGUMENT IN CONTEXT: AN ANALYSIS OF PROCESSES OF CONTEXTUALIZATION IN INTERACTION

Ann Ryu

University of California, Berkeley

annryu@socrates.berkeley.edu

In this paper, I will report on an analysis of a group of undergraduate calculus students working on the construction of a mathematical argument. The analysis is centrally concerned with how participants use the *context of ongoing interaction* as a resource for their mathematical meaning-making. I borrow the sociolinguistic notion of *frame* (Goffman, 1974; Tannen & Wallat, 1993) to highlight the construction and use of context in the participants' activity. The analysis demonstrates that, in the collaborative development of a mathematical argument, (1) participants interactionally construct frames of interpretation through sequences of claims-assessments-justifications in talk (Goodwin & Goodwin, 1992), and (2) the coordinated use of talk, gesture, and representation serves to re-frame mathematical work, supporting the generation of new understandings of the mathematical activity. I will conclude with implications of analyses in the sociolinguistic tradition (and this analysis in particular) for understanding and improving the teaching of mathematics.

## Introduction

Mathematical discourse in classrooms has increasingly become a focus of reform and research in mathematics education. Mathematics classrooms can be seen as communities in which the standards, norms, and practices of the communities of practicing mathematicians are developed and supported. As such, the fostering of mathematical discourse—the disciplinary discourse of the larger mathematical community—is a central focus of some classroom reform efforts in mathematics classrooms (NCTM, 2000). The processes of mathematical justification and argumentation are among the aspects of mathematical discourse that have received attention in reform efforts and the research literature (Harel & Sowder, 1998; Lampert, Rittenhouse, & Crumbaugh, 1996; Schoenfeld, 1985). Effective mathematics instruction should “de-emphasize the transmission of factual or otherwise incontestable information from teachers to students and should encourage the active involvement of students in discussing ideas, making convincing arguments, reflecting on and clarifying their thinking” (Forman, Larreamendy-Joerns, Stein, & Brown, 1998, p. 528).

However, despite an increasing rich body of research addressing mathematical justification and argumentation in classroom interaction (Forman et al., 1998; Hall & Rubin, 1998; Lampert, Rittenhouse, & Crumbaugh, 1996; O'Connor & Michaels, 1996) the nature of *in situ* mathematical justification from the students' perspectives is still not well understood—what and how students decide what is convincing, what is necessary to an argument, and what counts as valid in mathematical argumentation.

As with any social interaction, these issues are negotiated in ongoing interaction by the participants within their particular settings (social, cultural, historical, and technical). Understanding students' mathematical activity, in particular in reform environments that are organized to foster aspects of mathematical discourse, involves the examination of how students interact and collaborate to construct situated meanings of the mathematics. As such, the *context of ongoing activity* as a resource for participant interpretation should be a primary focus of an analysis of mathematical meaning-making (Cobb, 2000). In this analysis I will borrow the sociolinguistic construct of *frame* to highlight the construction and use of context in ongoing mathematical activity. How participants collaboratively construct frames for understanding their work and how those frames shift in ongoing activity are the central questions in this investigation of students' joint construction and evaluation of mathematical argument.

### **Theoretical and Analytical Orientation**

This paper is centrally concerned with how *context* shapes and is shaped by ongoing interaction. Although the notion of context holds a wide variety of meanings in different research perspectives, for my purposes, context is the set of relevant psychological, cultural, environmental, and technical resources that participants bring to a situation to attempt to accomplish particular goals or make meaning of an interaction (adapted from Van Oers, 1998, and Goodwin & Duranti, 1992). This is not to suggest that all the participants in a particular situation necessarily hold the same meaning of the interaction or are deploying the same set of contextual resources. An individual makes particular situated meaning of her activity supported by that context in which that meaning is functioning. Neither is context static or objectively determined by the characteristics of the situation. Contexts change what is considered relevant to an activity and what can be drawn upon to support that activity changes. And, finally, these changes do not occur independently of the participants and their activity; participants "dynamically reshape the context that provides organization for their actions within the interaction itself" (Goodwin & Duranti, 1992, p. 5).

How is this *process of contextualization* accomplished? How do interactants collaboratively construct contexts that support the situated meaning-making of their activity? How do they use context to make meaning? One approach to this question, rooted in Activity Theory (Engestrom & Miettinen, 1999; Van Oers, 1998), emphasizes *activity*—the interaction of participants and their purposive use of resources to accomplish goals—as the context for particular actions that provides resources for appropriate interpretation of those actions. Further, as the activity system shifts (as a consequence of the completion of an objective, in response to changes in the environment, in order to accommodate changes in the interaction order, etc.) the context of the interaction shifts. Thus, the set of relevant resources with which interactants make meaning of particular actions is reshaped via the previous actions of the interactants themselves—actions provide a frame for interpreting subsequent actions (Van Oers,

1998, p. 480). In discursive activity, talk, gesture, and purposive tool use can be seen as forms of action. Interactants shape context and are shaped by context through their talk, use of gesture, and use of cultural artifacts, which serve to accomplish goals in ongoing activity (Hall & Greeno, 1997; Saxe, 1991).

In this analysis, I will be using the sociolinguistic notion of *frame* to describe the construction and use of context in ongoing interaction. In the most general sense, Goffman (1974) has defined frames as “schemata for interpretation” or “the organizational and interactional principles by which situations are defined and sustained as experience” (p. 21). In other words, a “definition of what is going on in interaction, without which no utterance (or movement or gesture) could be interpreted” (Tannen & Wallat, 1993, p. 59). Frake (1977/1997) warns, however, that frames should be seen as accomplishments of *interaction* through which people “propose, defend, and negotiate interpretations of what is happening” (p. 37). Similarly, Tannen and Wallat (1993) argues that since interactants communicate messages about “what is happening” by their behavior, “frames emerge in and are constituted by verbal and nonverbal interaction” (p. 60). Thus, frames are resources for ‘seeing’ or making meaning of ongoing interaction that are interactionally constructed via the actions—both verbal and nonverbal—of the participants. Thus, the process of *contextualizing* can be seen partly as a problem of framing.

The notion of frame has recently been used to examine discourse in mathematics classrooms, and argumentation in particular. In their analysis of how a teacher frames collective argumentation in a mathematics classroom, Forman et al. (1998) use the concept of frame as a way to understand the development of the shared expectations among community members about mathematical argument. They focus on how the students bring different frames to the discussion, and how the teacher re-frames the activity through revoicing moves. I will be using the notion of frame in a related but somewhat extended fashion—not only as a way of talking about how the participants interpret the kind of activity they are engaged in (e.g., collaborative problem-solving, collective argumentation), but also how the participants are interpreting, or ‘seeing’, the objects of the activity—the mathematics.

### **Data/Participants/Setting**

The study was conducted in a discussion section of an introductory calculus course where the sections were organized as “workshops” (Fullilove & Treisman, 1990). In these sections, students worked in small groups at blackboards during problem solving sessions while the graduate student teaching assistants (TAs) were expected to actively support student interaction and to emphasize the need for mathematical explanation and justification. With the TA of our focal section, we selected one group of three students and several problems assigned during the section for close analysis. We chose problems that explicitly required proof or justification and that contrasted analytic/geometric content in their design. The subjects of the study are

three undergraduate students—two female (Ariel and Amy) and one male (Josh)—and a male graduate student TA (TK). The data was collected in a university classroom in which this section was regularly held. There were a total of about 24 students in the section and they worked at the blackboards in groups of 3 or 4. Data consist of (1) field note observations of three weeks of section (six sections total) that occurred about a third of the way into the semester, (2) primary video and audio recordings of the group during the two days when the groups were working on the focus problems, and (3) video-elicited interviews subsequently conducted separately with the group of students and the TA. Selected video/audio segments from the group's problem solving session in their section were reviewed and served as the basis for a common set of semi-structured questions for these interviews.

### Orientation to the Episode

For this paper, I will focus my analysis on one particular episode during the two days of problem solving that were videotaped. On the day of this episode, the discussion section is working on problems from the problem sheet "Monotonicity and Concavity." At this point in the course, they had covered the concept of derivative and some applications of derivative (especially curve sketching). The episode consists of the students' work on part (b) of the third problem they worked on that day, a three part problem about the quadratic polynomial: (a) Show that a quadratic polynomial  $f(x) = ax^2 + bx + c$ , where  $a$ ,  $b$ , and  $c$  are real numbers, always has one critical point and no points of inflection. When is  $f$  concave up? When is  $f$  concave down? (b) How can you tell if a quadratic polynomial has two roots? One root? No roots? (c) Suppose that  $f$  has two real roots,  $r$  and  $s$ . Show that  $f'(r) + f'(s) = 0$ . Also show that the critical point of  $f$  is midway between the two roots.

Part (b) is intended to be a derivation of the discriminant test for the number of roots of a quadratic polynomial, starting from the relationship between the critical value and the concavity. One possible way to approach the problem is on a case-by-case basis, considering the conditions on the critical value and concavity for each of the three cases: two roots, one root, and no roots. This approach requires a geometric understanding of the relationship between the concavity of the parabola, the location of its critical point, and the  $x$ -intercepts of the parabola.

### Analysis of Episode<sup>1</sup>

#### Phase One: Making Sense of the Task (lines 1-57)<sup>2, 3</sup>

This episode begins as the students turn their attention to part (b) of the problem. Amy reads the problem aloud—"how can you tell if a quadratic polynomial has two roots, one root, or no roots." Josh and Amy each suggest possible methods of approaching the problem: factoring, using the quadratic formula, and using the discriminant. There is some discussion (and a misidentification) of the discriminant, but Josh and

Ariel soon agree that these methods are not appropriate for this task—they should not have to “remember back to algebra” to solve this problem, and they should be using “stuff that we know how to do right now,” i.e., calculus. Josh then considers whether one can tell anything about the roots of a quadratic polynomial, which is what the task is asking about, from the derivative, which is what they are currently studying; Ariel and Josh tentatively dismiss this notion. Ariel then suggests graphing “it,” and Josh responds with a short laugh and reiterates that “there are a lot of ways but it seems like they want us to use calculus and not (.) um algebra.” After some moments of silence, Josh suggests that they “imagine a quadratic.” After a brief pause, he produces an explanation, in talk and gesture, of when a quadratic has no roots—“since it only has one maximum, it only has a maximum or a minimum (.) right? then if the maximum is greater than zero then...it has no roots.” This statement is immediately questioned by Ariel (“well...it depends”). Finally, Josh produces another explanation, again in talk and gesture, that describes when an “open up” parabola has no roots (“it’s greater than zero”), one root (“if it’s equal to zero”), and two roots (“if it’s less than zero”).

### **Constructing shared frames for seeing: How talk and gesture shape context.**

For most of this first phase of the episode, the students can be seen to be negotiating a way of seeing this task—a way of seeing that is relevant in and appropriate for their particular situation as calculus students solving problems in this section. In other words, they have framed their task as one involving the mathematics of calculus. How is this work of framing achieved? How is the negotiation of a shared frame of understanding accomplished in interaction? This discussion of phase one highlights the participants’ use of particular structures in talk to interactionally construct context; specifically, how sequences of *claims/suggestions*, *assessments*, *justifications*, and *repairs* construct frames for shared understanding of activity. Before beginning the discussion, I will illustrate how I used these constructs in the analysis. *Claims* are assertions of fact: “no you shouldn’t you can’t tell anything about the roots from the derivative...” or “well, thats one of those places that you can’t use the: the second derivative test...” *Suggestions* are statements that suggest the possible utility of some idea or procedure: “you can (...) isn’t there that discriminant thing...” or “graph it and?” Throughout the episode, claims and suggestions were used to introduce ideas, concepts, or methods into the context of the ongoing interaction.

Following Goodwin and Goodwin (1992), *assessments* are seen to be statements or other types of action that (implicitly or explicitly) evaluate the claim/suggestion, usually affirming or rejecting it with some justification. In the simplest case (without justification), a claim is affirmed or rejected and the activity progresses:

Josh: (4) no you shouldn’t you can’t tell anything about the roots from the derivative (.) can you? (3) the roots of the for of the form of the // function] itself?

Ariel: //no:::]

In another example, Ariel's suggestion is implicitly rejected by Josh and this assessment is justified on the grounds that her suggestion is inappropriate:

Ariel: graph it and?

Josh: ((LF)) (2) there are lots of ways but it seems like they want us to use **calculus** and not (.) um algebra

A turn sequence of claim/suggestion-assessment-justification can sometimes include repairs which then serve as claims that are also evaluated. In the following example, Josh gives a verbal and gestural explanation of the conditions under which a quadratic polynomial has no roots, a claim of fact. Ariel challenges his claim ("it depends"), implying that his statement did not sufficiently address the conditions necessary for his conclusion. He then repairs his initial claim, again employing both talk and gesture, producing a statement that is more complete, coherent and consistent in structure (lines 41-57):

41 Josh: =if the (.) it's [since it only has one maximum]

42            *[{traces a concave up parabola in space}],*

43           it only has a [maximum or a minimum (.)] right?

44 *[{points above and below the traced parabola}]*

```

45         then if the [maximum is greater than zero]

```

46 *[[points to a 'maximum' then points down to 'zero']]*

47 Josh: //then] right then //then] [it has no roots]

48 Ariel: //oh] //well] [*points to a point above 'zero'*]]

49 Ariel: //it depends]

50 Josh: //if it's]

[if it's ] whatever [if it's open up] right?

51       $\{traces\ cc\ up\ parabola\}$        $\{traces\ cc\ up\ parabola\}$

52           and [it's greater than zero then it has no roots]

53            *[[points to a point above 'zero' in space]]*

54 [if it's equal zero then it has one root]

55      *[[points to 'zero']]*

56 [if it's less than zero then it //has:] two roots.]

57      *[[points below 'zero']]*

By identifying the occurrences of these kinds of turn sequences and their relations to each other in the ongoing interaction, we can see how shared frames are interactionally constructed. As claims are made, evaluated, and repaired, the frame of activity shifts or is refined, thereby shaping the kinds of claims that can subsequently be made and how they are evaluated. In this way, the participants negotiate in ongoing interaction the space of possible contexts and content, mathematical or otherwise, in and with which they do their joint work.

As mentioned above, this phase begins with Josh suggesting two possible approaches to investigating the roots of a quadratic polynomial, which he is then immediately skeptical of—"by factoring generally by using the quadratic formula (.) (but??) ((LF))." Overlapping Josh's expression of doubt, Amy begins to suggest "the discriminant," though she self-repairs twice, softening her statements with each repair, until she finally asks "what's the discriminant." Josh then implicitly evaluates and rejects these suggestions on the basis that they should not need to appeal to content from previous mathematical experience: "we should be able to do it without having to like (.) remember back to..." At this point in the interaction, we see that Josh is beginning to frame their task as one located in the present, without having to reach back to concepts like the discriminant or methods like factoring or using the quadratic formula. Ariel immediately agrees and Josh elaborates: "it should it should it should show us this without having to like (.) remember back to algebra." Overlapping with Josh's utterance, Ariel then asserts that "it should be stuff that we know how to do right now." Josh's next utterance and shift in gaze—"so:: *[looking at the board]*"—indicates that he has resolved for himself a way of understanding what realm of mathematics is relevant for their task and is moving on. This extended and overlapping turn sequence shows that Josh and Ariel are interactionally constructing a frame for understanding their activity. By limiting the space of possible approaches to those involving the current content, which at this point in the course involves derivatives, they have established a frame within which subsequent claims regarding the specific mathematics of the task are generated and evaluated. However, they have not yet have a way of *understanding* the mathematics of the problem; they must further refine their shared frame and use it as a resource for seeing how one can tell the number of roots of a quadratic polynomial.

Josh next begins to consider a hypothetical ("if it has") which Ariel picks up ("if it has two roots then::"). Josh then responds with "no you shouldn't you can't tell anything about the roots from the derivative (.) can you? (3) the roots of the for of the form of the function itself?" It is significant that this is the first time that the word "derivative" is mentioned in this episode. It is a reasonable conjecture that Josh is making a self-assessment of his own hypothesized consideration of the roots of a quadratic polynomial in relation to the derivative, answering the unstated question "can you tell anything about the roots of a quadratic from its derivative." His negative self-

assessment highlights the salience of the frame (he is now considering how concepts in “calculus” not “algebra” relate to the number of roots) as well as his current framing of the task—as one in which derivatives are important players. Ariel then agrees with this statement and Josh restates his claim tentatively: “I don’t think you **can**” At this stage, Ariel suggests that they “graph it?” to which Josh responds “((LF)) there are lots of ways but it seems like they want us to use **calculus** and not (.) um algebra.” Josh is clearly assessing Ariel’s suggestion as inappropriate (and perhaps even laughable). Though it is not obvious what Ariel meant by “graph it,” it seems clear that Josh interprets this from the “calculus” frame and rejects her suggestion, reiterating that it is the current “calculus” material that they should use rather than “algebra.”

However, her suggestion to “graph it” has introduced another element into their frame for understanding the task—the graphical representation of the quadratic polynomial. As he stated in the interview after viewing the videotape, “it’s possible that Ariel cued me with hmm saying “You should graph it,” or something like that, ‘cause then I started thinking about the shape of the quadratic.” In the next utterance (line 37), Josh suggests “well let’s imagine (2) a quadratic,” an invitation to the other participants to join him in visualizing a quadratic function, to imagine the graph of the function. And he does, in fact, through this new frame, start to see “how it should be conceptually.” His statement in lines 41-47 (see above), his first try at an explanation, draws upon a geometric understanding of the situation, the language of derivatives (“minimum,” “maximum”), and gestures illustrating and clarifying his talk.

With this performance, he appears to have not only produced an explanation of how you can tell if a quadratic polynomial has no roots which locates the quadratic in the realm of “calculus,” but also created a shared frame for Amy and Ariel by animating the parabola in a plane in shared gestural space. They can *see* how he sees it because he has literally drawn his way of seeing for them. It is plausible that Ariel’s overlapping response of “oh” (line 48) indicates that she is also seeing a way of understanding how you can tell if a quadratic has no roots (Schiffrin, 1994). This interpretation is corroborated by her subsequent challenge: “well...it depends” (lines 48-49). Josh’s performance in lines 41-47 is not unproblematic; what he is saying—that if the parabola has a maximum above the x-axis then it has no roots—is the not the case for the concave up parabola he is gesturing. A concave *down* parabola has no roots if its maximum is above the x-axis, and a concave up parabola has no maximum at all. By saying “it depends,” Ariel shows that she understands that his explanation depends on the concavity of the parabola, and that what he is *saying* is only true for a concave down parabola. She is sharing his frame for understanding the problem, but is pushing for further refinement of the explanation. Finally, he repairs his explanation, producing an argument that is more coherent, structurally consistent, and complete (lines 50-57 above).

This first phase ends with a fairly clear verbal and gestural expression of Josh and Ariel’s current frame for interpreting this problem. It involves concepts in calculus that

they have recently studied (extrema (maxima/minima) and concavity), is based upon a geometrical understanding of quadratic polynomials and derivatives, and is organized in a logical case-by-case structure. As will be seen, this way of seeing the problem is carried by the participants and used to accomplish further objectives in their activity. It is not merely an explanation, a historical artifact in their ongoing interaction, but a way of seeing that they come to use flexibly as a contextual resource.

### **Phase Two: Writing up the Argument (lines 58-122)**

This second phase begins after Josh's final explanation as the focus of the activity shifts to the blackboard. Ariel begins writing down symbolically the first of the cases that Josh has just explained. She writes "if  $a > 0$ " (concave up) and the condition that the critical point is "greater than zero"—meaning that it is above the x-axis—which she represents as " $-b/2a > 0$ ." At Josh's suggestion, she has incorrectly taken " $-b/2a$ " to mean the y-value of the critical point; however, none of the students dispute this and they continue to jointly write up the conditions for each of the three cases in the original task: no roots, one root and two roots. At several points there is some confusion, in particular about the case of "one root" and what happens if  $a=0$ . At these points, Josh gives an explanation that satisfies Ariel and they continue constructing their table of cases.

### **Coordinating frames for seeing the mathematics to produce a solution.**

Throughout the episode, the participants coordinate their talk with gesture and representational use in order to not only elaborate and illustrate their speech but also to organize and support their understanding. In other words, coordinated talk, gesture and representations provide frames for interpreting their ongoing activity. At the start of this phase, an uncontested verbal and gestural explanation of one set of conditions under which one can tell whether a quadratic has two roots, one root or no roots has been produced. As stated earlier, the work that the students now begin is the transformation of this understanding into a complete, coherent, clear and durable representational artifact. This activity begins with Ariel announcing "so:", picking up chalk, and moving to the board. In doing so, she is implicitly affirming the existing argument and re-framing their activity to be one in which they will make durable and public what had up to this point been verbal and gestural. In the several minutes that follow, Ariel and Josh jointly produce a chart of the different cases of quadratic behavior. At the start most of this work is unproblematic—Ariel writes the condition and conclusion, narrating her actions: "if  $a$  is greater than zero which means it's (.) concave up { writes 'if  $a > 0$ ' on the board }." She is also sometimes directed by Josh and follows his suggestions without challenge. During these kinds of exchanges, their talk refers exclusively to the symbols being written and to features of the inscription itself. They are sharing a frame for seeing their activity, writing up an argument, and in what manner that argument should be represented, symbolically in a case-based logical structure.

As they continue, however, there are points of contention at which the nature of their interaction changes. At these points, their talk is no longer *in* details of the production of the table, but *about* the content of the table and how it is coordinated with other ways of seeing how the cases are organized. For example, Ariel and Josh run into difficulties when she proposes “ $a=0$ ” as a case. Josh responds by reasoning that if  $a=0$ , you will have a case where the second derivative test cannot be used. Rather than draw upon their geometric frame for seeing the cases, he uses a symbolically derived result from their work on part (a) of the problem, the second derivative test, to justify why they should not use  $a=0$ . And although Ariel affirms this reasoning, it is clear in lines 88-107 that she has not yet come to a stable way of seeing the cases symbolically:

- 88 Ariel: [if negative  $b$  over two  $a$  is equal to zero] (.) then [one root]  
 89           [*{writes  $-b/2a = 0$  underneath  $a > 0$ }*]       [*{writes ‘1 root’}*]  
 90 Josh: across the board (.) for [that one also]  
 91           [*{points to  $a < 0$ }*]  
 92 Ariel: no because=  
 93 Josh: =if it equals zero=  
 94 Ariel: = $a$  isn’t gonna exis  
 95 Josh: [if it’s if it’s concave up and it equals zero]  
 96           [*{makes cc up parabola with rt hand, then points to vertex of his parabola}*]  
 97 Ariel: right {draws dividing lines in grid}  
 98 Josh: then it’s then it has one root.  
 99           [if it’s concave **down** and the critical point equals zero (.) then it still has one root]  
 100           [*{makes cc down parabola with rt hand, then points to vertex of his parabola}*]  
 101 Ariel: right ok

In this strip, there is again confusion about the relation between “ $a$ ” and the “no roots” case, in particular whether or not “ $-b/2a=0$  and  $a < 0$ ” is a valid case of “no roots.” Rather than appeal to the second derivative test again, Josh re-frames the case in terms of their shared geometric understanding. He again provides referents for his verbal statements using gestural animations of a parabola, its vertex, and relation to “zero.” By re-framing the case in such a way, he is coordinating the geometric/gestural understanding they shared at the end of phase 1 with their current, somewhat unstable, way of seeing the problem in the symbolic/inscriptional arena. In his coordinated

performance, he not only displays his own competence with respect to moving in and between the multiple 'ways of seeing' this situation, but uses these multiple frames effectively enough to get Ariel to see the logic of the table more clearly and coherently. Thus, we see the refinement of Josh's verbal/gestural/symbolic coordination.

It is an important to note that during their work, the mathematical object " $-b/2a$ " takes on a meaning that is mathematically incorrect—that of the value of the critical point rather than the x-coordinate of the critical point. This object comes to represent something to them, via the coordination of gesture, talk and inscription, whose meaning is shared by the participants, yet is problematic in the view of normative mathematical meaning.

In this analysis we see that when the production of a particular inscription is unproblematic focus of the talk is on the inscription itself, often narrating what is being written. However, when there is disagreement about how to proceed or the accuracy of something written, the participants draw upon gestural and representational resources to help them re-frame their own or others' ways of seeing. In this way, the coordination of talk, gesture and representation can be seen to support the progress of the ongoing activity.

### Conclusions

By examining the processes of framing that these individuals interactively engage in during their mathematical work, this analysis highlights the contextual resources that individuals bring to bear in a particular activity and how participants re-construct, re-negotiate—in short, re-frame—their interactions as their activity evolves. As we have seen, participants' frames may shift when the objectives of activity are met and new objectives arise. As the focus of their activity shifts from making sense of the task to showing their argument (first part to second part), their geometric/gestural frame of reference shifts to a symbolic frame of reference, which are, of course, not unrelated ways of seeing, but ways are complementary and rely on different contextual resources. These frame shifts impact not only the mathematical (psychological, representational) resources that individuals draw upon, but also the social, cultural and historical resources that individuals find relevant in doing their mathematical work. In addition to frame shifts that arise out of shifts in the objectives of activity, participants' use of assessment moves in talk contributes to the collaborative construction of context through the ongoing negotiation of frames for interpreting further activity. As claims are made, evaluated, and repaired, the frame of activity shifts or is refined, thereby shaping the kinds of claims that can subsequently be made and how they are evaluated. In this way, the participants negotiate in ongoing interaction the space of possible contexts and content, mathematical or otherwise, in and with which they do their joint work. Additionally, their coordinated use of talk, gesture, and representation serves to re-frame their work in alternate 'representational worlds', supporting the generation of new understandings of the mathematics.

On a general level, this analysis underscores the collaborative and contextual nature of this kind of mathematical work. In these discussion sections, students and instructors are expected to engage in conceptually challenging mathematics and interact with each other about that mathematics so that the participants' thinking processes are made visible and mathematical justification is a norm of their problem-solving activity. These students make relevant aspects of their thinking visible to others as they work to frame and re-frame their ongoing activity, and through their assessment sequences in talk their justifications for mathematical claims are brought into conversation. Thus, to differing degrees, these students can be seen as skilled practitioners of this classroom culture who deploy various representational, language, artifactual, cultural/historical resources to engage in those practices. Although an analysis of the students-TA interaction is missing from this paper,<sup>4</sup> I believe that analyses of this kind can inform the design and implementation of classroom environments like these. As instructors are increasingly being expected to skillfully support and manage student-student and student-instructor conversations in ways that are mathematically rich, personally meaningful, and relevant, it is important that we have a nuanced understanding of how students engage in mathematical activity as they struggle to make sense of the mathematics and their identities as students of mathematics. With this understanding, instructors may be able to more effectively capitalize on students' ways of talking and seeing as they support and manage interactions around mathematical content.

### Notes

<sup>1</sup>In this following analysis, the episode will be presented in two phases. For each phase, I will first give a rough sketch of the events, then provide a fine-grained analysis of the construction and use of frames in each phase.

<sup>2</sup>Line numbers refer to the full transcript (not included for length reasons).

<sup>3</sup>Transcript conventions: , (.) short pause; (#) pause # seconds; . falling tone; ? rising tone; :: extended syllable; -- self-interrupt; = latching; no pause between utterances; **bold** emphasis/stress; // ] overlapping talk; [ ] overlapping talk and gesture; ( ) text in parentheses is unclear; ((LF)) laughing; *{italics}* gestures

<sup>4</sup>This is included in a complementary analysis of the data corpus.

## **ASSESSING STUDENTS' CONCEPTIONS OF REFORM MATHEMATICS**

Jon R. Star  
Michigan State University  
jonstar@msu.edu

Amanda J. Hoffmann  
Michigan State University  
jansenam@msu.edu

### **Introduction and Perspective**

As the use of NSF-sponsored, reform-oriented mathematics curricula has become more prevalent across the US, an increasing number of researchers are attempting to study the “impact” of reform. In particular, mathematics educators are interested in determining whether reforms are having the desired effects on students, particularly with respect to the learning of mathematical content and the improvement of attitudes about mathematics. In this effort, researchers have used a variety of methods, and have looked at a variety of variables, in order to assess the impact of reform. In many cases, such research assesses reform by looking closely at students’ scores on tests or their strategies for solving certain kinds of problems. For example, Riordan & Noyce (2001) assessed reform’s impact by comparing students’ scores on standardized achievement tests. Other researchers have used structured interviews, classroom observations, and more interpretive or ethnographic methods to assess the impact of reform (e.g., Boaler, 1997). Both of these methodologies are useful in assessing the impact that reform mathematics curricula are having on students. An alternative evaluation of the impact of reform that has not been as widely used is through the use of survey instruments. Surveys have been widely and reliably used to assess students’ motivation (Pintrich, Smith, Garcia, & McKeachie, 1993), beliefs and attitudes (Kenney & Silver, 1997), and interest (Köller, Baumert, & Schnabel, 2001). We propose to add to this literature by using a survey to study the impact of reform on students’ conceptions of mathematics.

### **Background**

Few survey measures have been developed for the purpose of studying secondary students’ conceptions of mathematics. One such measure is the Conceptions of Mathematics Inventory [CMI] (Grouws, 1994). The CMI is intended to assess students’ beliefs or conceptions about mathematics. Its 56 questions asked students whether they agreed or disagreed with certain statements about what it means to do, learn, and think about mathematics. The survey questions fall into seven categories (the composition of mathematical knowledge, the structure of mathematical knowledge, the status of mathematical knowledge, doing mathematics, validating ideas in mathematics, learning mathematics, and the usefulness of mathematics), each of which assesses a different aspect of students’ beliefs toward math. Students’ responses for each question were

between 1 and 6, with "1" expressing strong agreement and "6" expressing strong disagreement. A student who mostly agrees with all questions would seem to have an attitude that the survey designers felt was consistent with the aims of recent reform documents. Such a student would view mathematics as being composed of a useful, coherent, and dynamic system of concepts and ideas, where learning is accomplished by sense-making and authority is found through logical thought. A student who mostly disagrees with statements on the CMI would find mathematics an irrelevant, unchanging collection of isolated facts and procedures, handed down from a book or teacher, that must be memorized; this is a view that the CMI designers consider more typical of traditional math curricula.

Grouws and colleagues (Grouws, Howald, & Colangelo, 1996) gave the CMI originally to 163 9th, 10th, and 11th graders in traditional mathematics classes. Their intent was to determine whether students in advanced mathematics classes had different conceptions of the discipline than students in "regular" track. Although the questions on the CMI are intended to indicate whether students' conceptions are consistent with the goals of reform, the CMI has never been administered to a large group of students in reform mathematics classes to "validate" its effectiveness. In other words, although it may seem obvious that students with extensive experience in reform mathematics would have more reform-oriented conceptions than those with extensive experience in traditional mathematics, we made an effort to empirically explore whether students in reform and traditional settings would respond differently on a validated survey instrument.

In this paper, we describe our attempt to validate the CMI. In addition to providing evidence of the effectiveness of the instrument, such a validation also allows the CMI to be used as a measure of the impact of reform, in that it establishes "baseline" values for reform and traditional students' conceptions.

### **Method**

In conversations with the authors of the CMI (Grouws, personal communication, October 5, 2001), we became convinced that all of the 163 original respondents to the CMI (Grouws et al., 1996) came from traditional backgrounds in mathematics. In other words, although no data were collected about the schools, courses, or instruction experienced by students in Grouws and colleagues' original sample, we are confident that no student in this sample had any recent experience with NSF-funded reform-oriented curricula, and thus experienced something of a default approach to teaching mathematics that was more traditional than reform-oriented.

For the present study, and as a contrast, we sought to assess a sample of students who had as "pure" of a reform experience in mathematics as we could find. As part of our work in a number of teacher professional development and curriculum writing projects in Michigan, we developed relationships with several schools with exemplary enactments of reform curricula, particularly at the middle school level. Through these

connections, we recruited 134 9th grade students from a high school in Michigan to complete the CMI, early in their 9th grade year. All students completed at least three years of reform-oriented instruction (in 6th, 7th, and 8th grades) in a middle school whose curriculum (Connected Mathematics Project, Lappan, Fey, Fitzgerald, Friel, & Phillips, 1997) and instruction we were quite familiar with and that we are confident was an extremely well-enacted version of reform. Students were administered the CMI in their regular mathematics classes by their teacher.

### Results

To summarize our main results, we found that students from a reform background responded differently to the items on the CMI than did students from a traditional background. In particular, students' responses in the reform setting were more aligned with reform-oriented ideas on the scales of the CMI than traditional students' responses. Table 1 shows students' mean scores on the six scales of the CMI, for both groups of students. Recall that all items used a six-point scale, and that the lower the number, the more reform-oriented the response. The differences on each scale are statistically significant,  $p < .01$ .

**Table 1.** Participants' mean scores (standard deviations) on CMI scales

|                       | Compo-<br>sition | Structure     | Status        | Doing         | Validity      | Learning      | Useful-<br>ness |
|-----------------------|------------------|---------------|---------------|---------------|---------------|---------------|-----------------|
| "Pure"<br>traditional | 3.90<br>(0.9)    | 3.69<br>(0.8) | 3.69<br>(0.9) | 3.89<br>(0.9) | 3.96<br>(0.9) | 3.73<br>(0.8) | 3.50<br>(0.8)   |
| "Pure"<br>reform      | 3.34<br>(0.5)    | 2.76<br>(0.7) | 2.75<br>(0.7) | 2.65<br>(0.6) | 3.01<br>(0.6) | 3.01<br>(0.5) | 2.20<br>(1.1)   |

### Discussion

Our results provide evidence that the CMI is a useful and valid instrument for assessing the impact of reform. We found that after experiencing several years of exemplary instruction in a reform curricula, students do develop conceptions of mathematics that are aligned with NCTM reform documents.

Assessing the impact of reform is a complex endeavor, requiring the investigation of many aspects of students' experiences and using multiple methods. We believe that assessing students' beliefs about mathematics is vital to this effort.

## CHANGING THE WAY WE STUDY STUDENTS' MATHEMATICAL MEANING MAKING AROUND A GRAPHING CALCULATOR USING INNOVATIVE VIDEO DEVICES

Hector Morales  
University of Illinois at Chicago  
Hmorales@uic.edu

This short oral report intends to examine the innovative use of video devices as a research method for better understanding the nature and process of students constructing mathematical meanings as they use graphing calculators. A TI-Presenter was used along with a video camera to record students as they solved college algebra problems around a TI-83 graphing calculator. The TI-Presenter is a tool which allows graphing calculators to output the calculator screen to video media such as a TV monitor or VCR. In this way, it is possible to view what students enter into the calculator and to see the screen as students see it.

Current reforms in mathematics instruction set forth the expectation that students are to explore, discover, make conjectures, and negotiate mathematical meanings with others by sharing and communicating about mathematical objects and representations. Such learning activities are particularly important in advanced mathematics because secondary students encounter complex mathematical ideas such as functions that often require multiple representations such as tables and graphs. Furthermore, advanced mathematical topics often involve students using technological tools such as a graphing calculator which allows them to switch back and forth between the multiple representations of functions (e.g., Dunham & Dick, 1994; Lauten, Graham, & Ferrini-Mundy, 1994; Wilson & Krapfl, 1994).

Earlier studies which examined students using graphing calculators experienced difficulties in really understanding what students thought or how they came to understand complex mathematical ideas since it was not easy to see students' calculator screens or keystrokes (e.g., Doerr & Zangor, 2000; Wilson & Krapfl, 1994). The calculator screens and keystrokes could be thought of as windows into students' thinking. The TI-Presenter, a tool originally intended for classroom instructional purposes, solves the methodological problems experienced in previous studies.

With the aid of the TI-Presenter and digital video editing software, it was possible to combine and integrate multiple video data sources (i.e. the video data from small group interactions around a graphing calculator and the video data from the graphing calculator screen) into a "picture in a picture" format. This made it possible to view simultaneously multiple data sources while analyzing and interpreting data.

This was a critical methodological step for it allowed the researcher to record students' calculator screens and keystrokes as they used the graphing calculator. The significance of this methodological innovation is that it fills in a serious gap in understanding how students make sense of ideas such as end behavior or asymptotes

and how they use graphs and other representations to make this sense. The use of the multiple video data sources provides a much fuller and accurate account of students' developing mathematical understandings.

# **THE NEXT GENERATION OF EMERGING SCHOLAR PROGRAMS:IMPACT, REPLICATION, AND ADAPTATION**

Martin Vern Bonsangue  
California State University  
mbonsangue@fullerton.edu

David Eli Drew  
Claremont Graduate University  
david.drew@cgu.edu

This study examines the impact of Emerging Scholars Programs (ESP) on student achievement, faculty beliefs, and institutional structure in mathematics-based major programs. Based on a case study, this investigation identifies key program elements that may be critical for successful replication and adaptation of ESP programs in mathematics at other institutions.

## **Theoretical Framework**

In the early 1980's, Uri Treisman demonstrated the effectiveness of using highly structured workshop groups in the learning of calculus for African-American college freshmen (Fullilove & Treisman, 1990; Treisman, 1985). Drawing on the constructivist view of learning and the impact of social function on mathematics learning and self-efficacy, Treisman documented the effects of workshop participation on African-American students' achievement in first-year calculus. Bonsangue (1993, 1994) and Bonsangue and Drew (1995) replicated this result for a group of primarily Hispanic students majoring in science, mathematics, engineering, or technology (SMET), as well as documenting the positive effects of the program in the students' subsequent courses in their respective majors. In the ten years subsequent to Treisman's initial report, the workshop model, or Emerging Scholars Program, has been adapted for numerous professional and medical schools, universities, two-year and four-year colleges, and secondary schools across the country (Drew, 1996). Reports of the effectiveness and sustainability of such programs have varied considerably, based on the institution's expectations for success, structure for funding, and participation of students, key faculty, and institutional leaders. These reports have also documented the impact of such programs on faculty beliefs relative to student achievement, as well as fiscal benefits related to timely completion of degree requirements (Bonsangue, 1994, 1999).

## **Methods**

This study examined an on-going ESP program at the University of Houston and its impact on six participating institutions within the UH system which adapted such programs at for their own students. These institutions include both four-year comprehensive universities and two-year colleges. As part of a National Science Foundation grant awarded to UH, the authors served as external evaluators to the Houston Louis Stokes Alliance for Minority Participation (H-LSAMP) project. This study was based on data collected as part of that external evaluation.

The HSLAMP alliance includes The University of Houston, Texas Southern University, Southwest Texas State University, The University of Houston - Downtown, The University of Houston - Victoria, The Houston Community College System, The San Jacinto College District, Rice University and the Houston Independent School District. The first seven institutions are funded directly by NSF; the latter two institutions are project participants but do not receive federal funding.

Both qualitative and quantitative data were collected over a 1.5 year period from November, 2000, to May, 2002. Quantitative data included student achievement in SMET courses, institutional financial support, and faculty participation. Qualitative data included interviews with students, faculty, and site administrators. Results were based on comparison of student achievement, including graduation and transfer rates, with baseline data for each institution, together with both documented and perceived impact by faculty, students, and institutional leaders.

### **Results**

Initial results showed positive effects on student achievement and institutional adaptability for participating institutions. Interviews with participating students showed extremely enthusiastic support for the continuance and development of such programs. Interviews with faculty and site leaders showed enthusiasm mixed with concern relative to faculty rewards and fiscal priorities. Identifying specific areas of success and topics of concerns may help to clarify the critical elements of an ESP program to be successfully adapted and developed, not only at the institutional level, but at the system-wide and state-wide levels as well.

#### **Increase in SMET Degrees**

Based on discussions with AMP participants and leaders, it was evident that there was a strong consortium commitment to meeting the AMP goal of doubling the number of underrepresented minority graduates in science, mathematics, engineering and technology (SMET) majors over the next five years. Each campus had made considerable progress towards defining its specific goals and adapting its programs to identify and support AMP scholars who are planning careers in SMET disciplines. Moreover, in the first year of operation, the number of bachelor's degrees given to minority students in SMET fields increased dramatically from 458 to 640, a jump of nearly 40%.

#### **Importance of Outreach Activities**

One top administrator mentioned that many students define their first semester as a time to have fun—after all, for many this is their first time away from home—and, consequently, receive a low GPA which, then, undermines their future opportunities in college. Several of the STEM students with whom we met emphasized the importance of reaching out to high school freshmen and sophomores to let people know about the

options for support, mentoring, and achievement in college. Based on our conversations with students, faculty members, and staff at the LSAMP institutions, we can suggest several mechanisms that might facilitate more effective recruiting:

- Contacting high school students early in their career.
- Reaching out to home schooled students. Home schooling is a growing movement and these students represent an increasing segment within the undergraduate population.
- Communicating with high school counselors. The high school counselor, the person who advises students about college options, is a key person in the STEM pipeline. Counselors vary in quality and background, as do deans of instruction and head counselors. Perhaps special meetings could be held each year with the counselors, or head counselors, from all feeder high schools in the area, not just those high schools in the Houston Independent School District. Also consider personal phone calls and separate meetings with each of the counselors.

### **Strength of Diversity**

The SEP program at the University of Houston seems to be an enormous success. We met dozens of students who participate in the program, and interviewed seven of them at length. More to the point, we were able to visit the rooms in which the SEP program is housed and to observe the student culture created there. We saw a diverse group of students representing many ethnicities and different points in the college continuum, from freshmen to senior. It is clear that students are drawn to the SEP in part because of the community atmosphere that is created; that is, they are drawn in part because this is a fun place to hang out with friends. However, while the term is relaxed and friendly, virtually all students realize they are there for serious study. The result is that a student who seeks out the community and friendship of others in the SEP will find that the norm is to study and likely will find himself or herself working hard in STEM courses. As in all successful workshop programs, mentoring, working together on homework problems, and solving extra homework problems to excel, all are emphasized. We heard comments that the SEP “brings a lot of intelligent people together.” At the University of Houston, there are about 140 scholars, of which 50-75 are in their first or second year. One student said the SEP is “more than friends, a family.”

The University of Houston, under the leadership of Dr. Sylvia Foster, has created the largest, and arguably the most successful, SEP program in the country. The mentoring and community building activities at the University of Houston can be held up as a model for the rest of American higher education.

Most participants are students of color. Many are the first in their family to attend college. But their self-confidence, their achievements in STEM courses, and their aspirations are impressive. At the University of Houston, we talked with students

majoring in STEM disciplines who have serious aspirations toward graduate study, toward becoming teachers, a future attorney, a future physician, and a future astronaut (a graduate student at Rice also indicated aspirations to become an astronaut. Given the proximity of the Johnson Space Center, and the achievements of these young people in scientific disciplines, these aspirations do not seem unrealistic).

### **Role of Expectation**

The concept of aptitude often has been misused as an excuse not to educate many young people in mathematics and science. This is because many adults who guide and control the fate of young people in elementary and secondary school, e.g., teachers, counselors (and sometimes parents), often hold the erroneous belief that some groups of students lack the aptitude to master these subjects. These groups include girls and young women, students of color, and students from poverty. The data to show that, while the assumptions these adults hold about lower aptitude are invalid, these negative adult expectations often translate into organizational barriers that prevent students from taking certain subjects, and psychological barriers when the students incorporate those negative judgments into their self-images. Programs like the Uri Triesman (1985) workshops attempt to reverse the pattern: to expect students to excel and to create a mentoring and community support system that guides them toward achievement. At the University of Houston, we saw a wonderful example of how this type of program can succeed. We were told that the SEP students are welcomed by instructors, that the instructors know which students are in the SEP program (often from the t-shirts that they wear proudly), and that the instructors know that "we are smarter than the other students." This comment was made by the same student who acknowledged, in response to a question, that the SEP program is open to any student who wants to participate, and who meets some minimal standards. This is a classic example of the concept of aptitude being employed in a positive domino effect. Students join a community of scholars; they work hard to complete their assignments and to excel on tests; when they do so with the aid of the mentoring available through the community of scholars, they, and others, begin to assume that they are smarter than other students.

Just as high school students need to be told that they can be college material, that they can succeed in college, so, too, do undergraduates need to be told that they have what it takes to succeed in graduate school. We also discussed the need for successful STEM undergraduate and graduate students to balance the twin goals of successfully developing their careers while giving back to their community.

In the exit interviews that Southwest Texas State University conducts with LSAMP scholars who are graduating, they ask about the greatest benefit they received from the program. The most frequent responses center about leadership skills and communication and presentation skills

### Implications and Recommendations

Based on our visit and the documentation of the program, several specific suggestions emerged. These are relevant not only for the program under study, but as a national model for other programs as well.

1. The H-LSAMP is important, not only for its effects on student achievement, but for its effects on the institutions involved. The presence of the community colleges in the consortium makes both of these even more significant. Strong communication and effective cooperation between participating two-year and four-year institutions will play a major role in the success of this AMP. While discussions between neighboring institutions have begun, all H-LSAMP institutions are encouraged to work together to track the progress and success of AMP scholars that transfer from one institution to another. Typically, academic departments or schools are not directly involved with this process. However, direct involvement by AMP leaders will not only help facilitate a successful transition for its students, but will help define and measure the success of specific goals, such as doubling the number of SMET underrepresented minority students who transfer to a four-year institution.

2. Each institution should articulate in its strategic plan what activities it proposes in the areas of recruitment and retention, if it has not yet done so. Different institutions should, and will, emphasize each of these two activities to varying degrees. For example, in one of the larger institutions with substantial minority SMET enrollment in the junior and senior year, a greater increase in degrees could be linked to aggressive retention efforts, for a smaller investment, perhaps than recruitment efforts. At the other extreme, recruitment will be the first priority for institutions that currently enroll few minority SMET students.

3. Several of the institutions participating in the Houston LSAMP have successfully integrated the LSAMP student support program with their existing and ongoing programs, for example the SEP program at the University of Houston. This is an effective implementation procedure and we applaud the skill with which it has been carried out. However, it does make assessment and evaluation difficult, as it is sometimes a challenge to sort out the effects on a given individual, or group of individuals, of specific components of a highly effective group support program. For example, one of the most articulate students with whom we met at the University of Houston spoke about the contributions of the SEP program and made observations that, we're sure, apply also to the LSAMP program—despite the fact that she is not an LSAMP scholar.

4. Under the reasoning that the most successful students at four-year institutions will be those who attend full-time, LSAMP administration has required that awards be given only to full-time students. But the community colleges are a rich source of potential high achievers in STEM disciplines. Many of these students work full-time and have family responsibilities and other financial obligations. At best, some of them

can attend college only on a part-time basis. Relaxing the full-time requirement at community colleges so that these highly-motivated potential future scientists, mathematicians and engineers can receive some funding could have a dramatic positive impact on the success of this LSAMP.

### Summary

The development of ESP-type programs has perhaps been the single greatest factor underlying the mathematics reform movement in calculus at the university level (National Research Council, 1990; Selvin, 1992). Indeed, in 1992, Dr. Treisman was given a MacArthur "genius" award for his pioneering work in this area. The current study may be important because it examined and identified critical elements for initiating and sustaining ESP-type programs at the institutional and systemic levels. This study also documented the interactive effects of ESP programs on student and faculty beliefs and expectations.

# **LISTENING AS A VITAL CHARACTERISTIC OF SYNERGISTIC ARGUMENTATION FOR ENHANCED MATHEMATICAL LEARNING IN A PROBLEM-CENTERED ENVIRONMENT**

Darlinda Cassel  
University of Oklahoma  
darlinda.cassel@ou.edu

Anne Reynolds  
University of Oklahoma  
areynolds@ou.edu

From research observations of activities during a second-grade mathematics problem-centered learning environment classroom, synergistic argumentation emerged as a class norm for discussing the students' mathematics. In this paper we analyze the contrast between two students who were participants in this class. One student, Brett, depicts the use of argumentation successfully while the other, Miriam, depicts the use of argumentation ineffectively. An important aspect of Brett's argumentation was identified as hermeneutic listening. Brett's engagement enhanced the learning environment whereas Miriam's stance was counter-productive, at least for her.

## **Purpose**

Our research over the last several years has investigated a second grade mathematics classroom where the teacher has enacted a problem-centered learning environment (Wheatley, 1991; Wheatley & Reynolds, 1999). During the last three years we have focused in particular on the quality of discourse and argumentation that occurs during the whole class sharing time in each lesson. The two-fold purpose of the study has been to describe the mathematics whole-class sharing session and to analyze its function for effective learning occurring through conflict and disagreement in the open explanation of solutions and strategies.

In the second year of this investigation two students in particular provided us with contrasting pictures of discourse and argumentation during their involvement in this class. One depicts the use of argumentation successfully, while the other depicts the use of argumentation ineffectively. While our overall goal was to analyze the whole-class interaction patterns of a variety of students, focused in particular on the conflict of ideas and the ways of solving problems, in this paper we will describe and analyze episodes that involve these two particular students. By presenting their contrasting stances as they engaged in the sharing of ideas we propose that a deeper understanding of the nature of discourse and argumentation from the young student's perspective is provided.

## **Theoretical Framework**

In recent years there have been increasing numbers of investigations into classroom environments in which children talk openly about mathematics and explain their mathematical solutions in order for teachers to facilitate students' mathematical under-

standings. In this environment the teacher acts as facilitator and organizes instruction so that students are actively engaged in the doing and talking interactively about mathematics. The National Council of Teachers of Mathematics (NCTM, 1991, 2000) calls for students to construct meaning, learn different ways to think about ideas, reflect on and clarify their own thinking, and develop arguments.

The problem-centered learning environment classroom encourages students to collaborate and work together in developing mathematical communication based on openly shared mathematical activities (Wheatley, 1991). One characteristic of the problem-centered classroom is student small-group collaboration, where students work in pairs on problematic tasks for which solution procedures have not been provided or demonstrated by the teacher. Collaboration provides students opportunities to talk, to listen, and to negotiate not only the social norms (rules of behavior) but the socio-mathematical norms as well. The socio-mathematical norms are different from the social norms in that they are specific to students' mathematical activity (Yackel & Cobb, 1996), whereas social norms are rules of behavior developed and accepted by the students and teacher and can apply to any subject. In pairs mathematical meanings are under continuous negotiation as children work collaboratively to complete an assigned task. Mathematical meanings that arise between them are formed as part of their interactions within their small groups and then with the wider community in the whole-class sharing time.

Another characteristic of the problem-centered learning environment is the whole-class sharing time. The teacher and students negotiate mathematical meanings as they present their solutions and strategies and talk about their mathematics in this wider community (Cobb, Yackel, & Wood, 1992). The negotiation of socio-mathematical norms defines what kind of talk is valued in the mathematics classroom (Cobb, 1998; Kazemi, 1998). These norms are not rules that students must fulfill, but they deal with the process of making mathematical contributions toward learning.

Mevarech (1999) argues that collaboration and whole-class sharing allow children to learn through opportunities to explain, justify, and listen to one another's ideas. Further, he contends that explanations are the best means for elaborating meaning and making connections. These conditions help students to construct rich networks of meaning. As students share their explanations they must actively communicate with each other and the teacher. In order for that communication to be successful, they must negotiate meanings, not just recite facts. As they negotiate they adjust their interactions by presenting rationales for their strategies. Working together gives rise to learning opportunities as students express their thoughts while attempting to understand each other's ideas.

In a culture that demands students' understanding, teaching is more than merely informing or demonstrating for pupils. Teachers must enable pupils to create meaning through their own thinking and reasoning (Wood, 1999). Teachers and students

facilitate mathematical discourse by questioning and challenging each other to defend answers. In this way students have opportunities to talk about what they hear and understand and learn from one another's interactivity, and are not limited to just taking turns in a discussion (Kazemi, 1998). Their discussions relate to the mathematics at hand, making comments to gain understanding and/or clarification.

### **Setting for this Research**

This research was conducted in a second grade classroom in a low to middle income suburban public school that was also a site for the district's emotionally handicapped program. The students were from various backgrounds and had varying abilities and disabilities. The teacher had enacted a problem-centered learning environment for a number of years (Wheatley, 1991; Wheatley & Reynolds, 1999). The research reported here is part of a three-year study into the discourse and argumentation process students engaged in during the whole class portion of their mathematics class. The data analyzed here is taken from the second year of this study.

### **Methodology and Data Sources**

To frame this research, we used Cobb and Steffe's (1983) teaching experiment methodology where the researcher is a facilitator participant observer, working with the teacher and students, and listening to their interactions and ideas (Steffe & Thompson, 2000). We observed the second-grade mathematics lesson at least one day each week throughout the school year, monitoring and questioning students where appropriate to clarify their thinking. Extensive field notes were taken during each observation period and supplemented by video recordings. Observations of students in their small group problem solving, as well as interviews with teacher and students, provided a variety of explanations and interpretations during the whole-class events. The individuals' and groups' mathematical activity are interdependent. Therefore, students' participation in the small groups and the whole-class discussion gave insights into their mathematical development, and supplemented and helped when interpreting the whole-class discussion in greater depth. Particular attention was given to the mathematical activity during the whole-class discussions in which discourse was prevalent in students' construction of mathematics.

A constant comparative method guided the analysis of socio-mathematical interchanges that might lead to individual mathematical constructions (Strauss & Corbin, 1998). After each session, we examined the whole-class discussion data, which was first separated into specific event sections as frames in which to focus subsequent classroom observations, interactions, and interviews. Independently, we coded and categorized each of the data sets within each event, looking for regularities and patterns in the discursive process of students across the sets. Using the constant comparative method and more than one analyst's coding furthers the study's trustworthiness or fidelity by considering the classroom in its natural state without prior presupposition (Schwandt, 2000).

### Analysis of Data

It should be noted that when the majority of the students entered the second-grade they were not used to presenting their solutions to the class in the ways they were now encouraged to do in this second-grade mathematics classroom. Although they had been encouraged to share their solutions and strategies previously their sharing experiences during their first-grade year had been more like those attributed to Ms. Andrew's class in Kazemi (1998) or as McClain & Cobb (2001) reported. They were used to taking turns to present their solution strategies but had not been encouraged to critically listen to and challenge their own and other students' ideas. Much of the focus of the first few weeks in second grade, particularly during whole-class discussion, was on the negotiation of social norms including listening, making sense of others' explanations, asking questions of clarification, and challenging ideas that were presented by students and the teacher (Geoghegan, Reynolds, Lillard, 1997).

As the students began actively explaining, justifying, and questioning, synergistic argumentation (Cassel, 2002) emerged as the norm for the mathematics discussion, and this argumentation focused on mathematical constructions. There are several characteristics of synergistic argumentation such as interactive and open communication, reflection, listening, meaning making, and adjustment of intentions. These are all interwoven in the argumentation process of this problem-centered learning environment. During the argumentation process students are involved in learning what others expect of them in terms of participation as well as learning mathematics. Ideas are laid out in the open for others to make sense of. In this type of discussion emphasis is on the students' ways of knowing.

The emergence of synergistic argumentation brought about opportunities to observe changes in how students participated in the whole-class discussions. Whereas at first it was simply turn-taking, as teacher and students negotiated what was expected and that sense making was the focus, students began to listen and ask thought provoking questions. They were willing to actively participate without the teacher having to call on them. They knew sense making was valued and expected. They became uninhibited about explaining, justifying, or questioning. The teacher's role as an interactive facilitator, discussion stimulator, and encourager helped to develop a high level of open interactive argumentation among students that became the norm for this second-grade class. However there was one notable exception that became a focus for our analysis. As we observed students explaining and justifying their solutions, two students' actions emerged portraying a contrast between interactive arguing and turn-taking. These two students, Brett and Miriam, were both competent in mathematics and at times demonstrated sophisticated mathematical thinking and solutions to tasks presented.

We observed a number of students, particularly Brett, who became more reflective and critical of their own ideas in response to others' questions and challenges of ideas

presented by others during the whole-class sharing time. However, each time we analyzed the episodes in which Miriam presented her solutions, we noticed a somewhat rigid stance as she adhered to her solutions in response to other students' questions and challenges. This occurred at times where her solution was "correct" as well as at times where her solution was "incorrect." For example on one particular occasion was when there was disagreement about the "correct" solution for the following task:

There are 8 red flowers and 4 yellow flowers. How many more red flowers are there than yellow flowers?

Some students thought the answer would be 4 and some thought it would be 12. The class gave explanations and justifications as they discussed both of these solutions. Brett and Miriam agreed with a few other students that the answer would be 4. Miriam at one point in the discussion reread the task orally and stated, "It is take away." Another student said, "No, it says *more* so it is not take away." The teacher at this point asked Miriam, "Can you prove to them that it is take away?" Miriam's *partner* drew 8 circles in a column with a column of 4 circles next to it. A line was drawn under the first 4 circles in both columns leaving 4 circles below the line, thus indicating that 4 and 4 matched and there was a set of 4 circles without a match (see Figure 1).

Figure 1

She explained that therefore, there were 4 more red flowers than yellow flowers. Miriam did not participate in the explanation of the solution either by commenting or by indicating involvement through her body language; she simply ignored what her partner was doing and saying. As the argument about whether the problem was "add" or "take away" continued several times Miriam simply restated, "It means to take away." Brett on the other hand offered three different explanations of why the answer was 4. For example he drew the following on the board (Figure 2):

Note that his drawing is not the same as Miriam's partner had presented earlier; instead it provides a different justification in support of subtraction. In pointing to the 2 rows of red flowers (shaded circles in his drawing) he says: "8 of these....how much more red than yellow? So it means 4 more red than yellow (as he points to the extra row of red)." Later, he tries again in a slightly different way, referring to each row in

Figure 2

his drawing (from left to right) as he says: "This is one row, this is one row, and this row is left" as he tries to explain that one row of yellow flowers matches one row of red flowers and that there is still one row of red flowers left.

Brett took into consideration what others said and then re-explained trying to help other students understand why the task was to subtract. Although she was one of the

few students who believed at this stage that the task was one of subtraction, Miriam did not try to help Brett explain nor did she try to re-explain the columns of circles from either her partner's or Brett's drawings. This was one occasion early in the year where our subsequent analysis of the dialogue and the videotape of the discussion showed that all of the class was engaged and interactively participating in the argument, trying to make sense of each others' ideas and proposing counter arguments in an attempt to resolve this conflict, that is all except Miriam.

As a result of our noticing Miriam's rigid stance, the teacher initiated a variety of strategies to try to challenge Miriam to become more reflective and critical of ideas, but by the end of the year we saw very little change in her stance. This is clearly evident during one particular episode when students were given the following task:

From research Mrs. Stolt's class discovered that there are three basic fingerprint patterns: loop, whorl, and arch. After the 18 students recorded their thumbprints, they discovered there were two 2 more loops than whorl thumbprints. There were 5 less arches than whorl thumbprints. How many loops, whorls, and arches?

In this particular episode several students willingly volunteered to share their ideas, including Brett and Miriam. Miriam explained her solution and Brett and a few other students questioned her solution. Brett and Miriam became intensely "locked" into a stalemate while discussing each other's solutions during this particular episode. Brett's solution was correct but Miriam's solution was incorrect. She was just stubbornly arguing in favor of her own solution and was not listening to Brett as he tried to explain his strategy in arriving at his answer. What Brett was saying was going past her, she was not listening.

Brett: (Wrote on the board 9, 7, 2.)  $9 + 7 = 16$ , 9 and 7 are like our class then add 2 more. I knew because on paper it said 3 less...and 5 more than whorl is 2.

Miriam: (Drawing tally marks on the board.) ...there are 18...6 arches because 2 more loops than arches so 6 here and 8 here then whorl added 4 more.

Both solutions equal 18. It is not clear at this stage whether they had made sense of the task because they have given numbers, but with no explanations.

Two other students disagreed with Miriam's solution. She ignored them. From her perspective, she has demonstrated her solution method and sees no need to respond to either one. From a "turn-taking" perspective all she needs to do is state her solution without listening to others. The two students put their solution on the board without an explanation.

Miriam: Can you prove it up here?

Brett: (Reads part of the problem over again.) Because it says 2 more loops than whorls, not arches.

Miriam: (Has her back to Brett the whole time he is talking, and she is doodling on the white board.) more loops than whorls...

Teacher: Did you hear what he said?

Active listening involves body language as well as verbal reply. The teacher notices Miriam's stance. The teacher and students have negotiated that sense making is important. The teacher looks at Brett indicating for him to continue. In this way the teacher is reinforcing that the students are to make sense of the mathematics.

Miriam: No!

Brett: (Waits for her to turn around. When she does he then rereads the problem while looking at her.) 2 more loops than whorls...

Miriam: What!!

Brett: On the paper it says there are 2 more loops than whorls.

Brett rereads the task to bring into focus the question asked. By doing this, he gives Miriam, and the rest of the class, a chance to hear and reflect on what is being said.

Miriam: There is!! On my paper there is 2 more arches than whorls. There is because 2 more equals 6...so there is!!

Brett: Loops than whorls?

Again Brett tries to use another approach to help Miriam see the conflict. This time he repeats two significant words in the question instead of the whole question, thus highlighting the specific part Miriam needs to look at. He is again bringing the focus back on the task, hoping she will realize she has arches, not loops.

Miriam: Same thing, that's the same thing! (a bit irritated)

Brett: 5 more.

Miriam: 2 more that's it, that's the same!

Brett: 5 less arches than whorls and that's 2 more. (Keeps trying to refer to the paper with it in his hand. He was trying to repeat part of the problem.)

Brett now uses Miriam's words to argue from her point of view. He is trying to help her understand her reasoning in comparison to what the task asks. Miriam becomes defensive and does not acknowledge his solution. She did not ask him how he got 5 thus, the argumentation process for sense-making was hindered.

Miriam: That's what I have!!! (She emphatically repeats several times, "That's what I have," but doesn't read the paper or asks him any questions.) That's the same!!

As other students listen to the argument, they try to follow along and make sense of the discussion. Several students try to aid in the sense making process. As each student understands what is being discussed, s/he interjects with important ideas. Miriam dismisses their ideas and tells them they can't prove it with the paper.

In a problem-centered classroom where argumentation has been negotiated as a norm, students listen eagerly to each other while they explain and justify their solutions. They know that each will have opportunities to comment and/or question what the others have done or discovered. In the literature two terms, taken-to-be-shared (Voigt, 1994) and taken-as-shared (Yackel & Cobb, 1996) have been used to describe the collective sense making process. In this particular second grade classroom, a difference between the two terms has emerged. In this classroom the ideas are laid out for everyone to try to make sense of. In this way the ideas are meant to-be-shared with all learners. This does not necessarily mean that the ideas will be shared. If a student is not listening or does not understand, how can the ideas be shared? For example in this episode, Brett and Miriam are discussing their strategies. His are laid out to-be-shared. But, at no time did Miriam share his ideas. She did not attempt to make sense of them and they had no common ground from which to communicate because she was not listening. Thus, the argumentation process was hindered.

In this situation Brett was an active listener using Miriam's words to restate the question trying to promote sense making for all involved in the discussion. He even repeated a significant part of the question, "loops than whorls?" in response to her explanation. He used *her* words to argue from her point of view. He tried to understand her reasoning in comparison to what the task asked. Miriam became defensive and did not acknowledge his solution or questions. Each time Miriam answered or responded to questions, her arms were crossed (closed minded) and she simply stated that she had the answer.

Following is a brief contrast of the two, active listening and not listening (See Table 1).

**Table 1**

| Brett                     | Miriam                    |
|---------------------------|---------------------------|
| looks at person talking   | does not have eye contact |
| rereads task              | ignores written problem   |
| questions answer          | gives definitive answer   |
| open minded               | closed minded             |
| positive body language    | negative body language    |
| uses other person's words | repeats her own words     |
| mutual adjusting          | no adjusting              |

## Discussion

This contrast between Brett and Miriam provided data supporting what happens when one person talks past another person versus when one person is truly engaged in discourse and arguing/talking to one another. During the thumbprint episode, Miriam could not appreciate the differences in the interpretation of the solutions, thereby causing an impasse. In argumentation, listening emerges as a critical factor. Substantive mathematical learning occurs when students experience conflict with their previous ways of knowing (Wood, 1996). When students are not listening actively they cannot make sense of their flawed thinking nor can they make sense of other students' thinking. Miriam had her whorls and arches confused in her solution. A couple of students tried to explain, asked her questions, and reread the task in hopes that she would see her error. She did not look back at the original task to show a relationship between her solution and what the task asked. Nor does she acknowledge the other students' solutions or questions. Her stubborn response of, "I have that as my answer," inhibited her from making sense of the situation, thus not changing her answer. Learning breaks down when interactive listening is not achieved.

Students in this whole-class argumentation process attempted to accommodate each other in listening for understanding, to properly orient each other's mathematical constructions and ideas for meaningful learning, and to resolve conflicting solutions. Davis (1997) states that hermeneutical listening is where the mode of attending has been negotiated to reflect the participatory manner of interacting with other learners. Listening becomes the attentiveness to the historical and contextual situations of the students' actions and interactions. The students who listen hermeneutically, as illustrated with Brett here, are willing to interrogate and to be interrogated, reflect, and adjust their thinking. Thus, students who listen hermeneutically further mathematical discussion and constructions. Listening is vitally important in argumentation because it aids the teacher and students in their understanding of each other's solutions, explanations, justifications, and questions. As they become aware of each other's perspectives listening enables them to ask appropriate and constructive questions that help to deepen their own understanding and each other's mathematical understandings.

Many times during the mathematics lesson conflicts of interpretation arise naturally as students give various answers, and in this particular class the teacher expects the students to resolve them. The students' own personal constructive activities are valued. The students in this class are also expected to make sense of ideas presented by other students. Thus, listening emerges as a key factor within this problem-centered classroom's mathematical argumentation process. The students, as listeners, are responsible for making sure they understand other students' explanations and justifications. In this way students are responsible for making sense of the mathematics as well as being active listeners. Active listening involves reflective thinking as students attempt to understand others' explanations and justifications.

In this whole-class argumentation students are attempting to accommodate each other in listening for understanding, to properly orient each other's mathematical constructions and ideas for meaningful learning, and to resolve conflicting solutions. We chose to label this open, mutually interactive and continually adjusting mathematical discussion "synergistic argumentation." As we observed this synergistic argumentation in action, and its positive effects on learning, we noted that an important aspect of its functioning is hermeneutic listening. If a student or students fail to listen, as with Miriam in this instance, it is easy for interactive mathematical communication to break down. This situation becomes evident when students talk past one another, if one is not listening to another, or if they are failing to make sense of other students' perspectives. Constructive interactions occur when both the sharer and receiver are actively involved in communicating and listening, which in turns help students develop mathematical understandings. Synergistic argumentation is more than talking about differences and misunderstandings, and it is more than seeing mathematics from various perspectives. It is the total interaction when students present their ideas and solutions, defend them in the face of questions, and question other students' ideas. In order for students to be able to defend and question they must be interactively listening or listening hermeneutically (Davis, 1997). Listening with the intent to understand creates a context in which the students are reflecting on their own methods while attempting to understand the other methods. Thus, it is up to the listening community of learners to ask questions, to agree or disagree or to make challenges, thus soliciting other arguments. As students listen interactively they become aware of interpretations from other students and continually try to adjust their thoughts and questions until understanding is reached among students. Hermeneutic listening provides opportunities for students to construct meaningful mathematics.

## **MATHEMATICS FOR PARENTS: FACILITATING PARENTS' AND CHILDREN'S UNDERSTANDING IN MATHEMATICS**

Marta Civil  
University of Arizona  
civil@math.arizona.edu

Cristi Guevara  
University of Arizona  
guevara@math.arizona.edu

Martha Alleksaht-Snider  
University of Georgia  
marthaas@coe.uga.edu

The study examines ethnically and linguistically diverse parents' learning in an eight-week Math for Parents course on fractions, decimals and percentages. Analysis of classroom observations, interviews, focus groups, written feedback, videotapes, and task-based/clinical interviews provided rich data yielding findings about both parents' affective and cognitive learning as well as their understandings of how to support their children's learning of mathematics. The research points to an appreciation among the parents for the importance of learning mathematics with understanding. It also raises some questions concerning the goals of mathematical learning experiences for parents.

### **Context**

Our research takes place in the context of a large parental involvement project in K-12 mathematics. MAPPS<sup>1</sup> (Math and Parent Partnerships in the Southwest) is a four-year long project that focuses on parental involvement in mathematics. It is now in place at four sites: in Tucson since 1999 and at the other three sites since 2001. The implementation at the different sites varies somewhat according to local needs, but overall we share some common goals. One such goal is to develop leadership teams (parents and teachers/administrators) that will help in the mathematics education outreach effort throughout the districts involved. We have three main types of activities related to our goal: a) Leadership development sessions for the members of the Leadership Teams; b) Mathematics Awareness Workshops (MAWS) ranging over key topics in K-12 mathematics and open to all the parents and children in a given district; c) Math for Parents (MFP) courses in which parents in the Leadership Teams and other parents have an opportunity to explore mathematical topics in more depth and to learn about reform mathematics and its implications for their children's education.

In this paper we consider our work in Tucson where we have three leadership teams in place and have offered a total of five Math For Parents courses. All the Math Awareness Workshops are currently facilitated by members of the Leadership Teams. In particular here we look at the experiences of an ethnically and linguistically diverse group of parents (all women) in one of the Math for Parents eight-week courses that was being taught for the first time. We discuss the affective and cognitive impact of the course that centered on developing an understanding of concepts related to fractions, decimals, and percentages. We also examine parents' reflections on their roles in their children's learning of mathematics (K-12) as they participated in this course. Research

on the effect of experiences such as these MFP courses on the participants' understanding of mathematics and on how they bring these experiences home to their children is particularly relevant for those of us concerned with equity issues.

### **Theoretical Framework**

Mathematics educators often stress the importance of involving parents as we embark on reforming school mathematics. These calls are predicated on the assumptions that parents have great potential to influence children's mathematics learning (Ford, Follmer, & Litz, 1998; Epstein, 1994; Henderson & Berla, 1994; Kliman & Mokros, 2001) and that parental support is necessary for successful implementation of reform mathematics programs (Kliman & Mokros, 2001). Researchers (Lehrer & Shumow, 1997; Peressini, 1998) have documented, however, the frequent mismatches between the aspirations of reformers in mathematics education and those of parents and other community members in the communities where reforms are being implemented. Peressini (1998) has observed "in both the larger arena of general educational reform and the subset of school mathematics reform, these calls for parental and community involvement have been at an abstract level and have not been closely examined" (p. 557).

We argue that in order to move beyond the abstract level in working with parents in mathematics, educators and researchers must begin by interrogating deficit models of parenting (Henry, 1996; Vincent, 1996) and question prevailing assumptions about the necessary skills base for parents' work with children in mathematics (Merttens, 1993). Our work reflects an awareness that, as Weissglass and Becerra (n.d.) write, "often classes or programs for parents are one-way transmissions of information and materials from school to parents. Rarely do parents, particularly those from groups underrepresented in mathematics, have an opportunity for their beliefs, ideas and concerns to be heard. ... All parents need a safe place to share and explore their early experiences with schooling, their thoughts about their children's learning, and their attitudes toward mathematics" (p. 2). Beyond discussions about learning, schooling, and mathematics attitudes, we have suggested in previous work that parents also need opportunities for meaningful learning of challenging mathematics content (Civil, 2001).

In addition to research literature on parent involvement, research on adult education, especially that grounded in critical pedagogy (Benn, 1997; Frankenstein & Powell, 1994) has been valuable in broadening the view of potentials for parent involvement in mathematics education. One of the key premises in this research is to view parents as intellectual resources. These researchers stress that there are different forms of mathematics and push us to reflect on what we count as mathematical knowledge, while suggesting pedagogical approaches that seem to be quite powerful when working with adults who have often been marginalized.

### Method

We followed a phenomenological methodology (Van Manen, 1990) that relies heavily on participants' contributions to the experience. The lived experience of each parent is considered significant and thus we try to capture it in our analysis and writing. Our sources of data include observations and field notes, interviews and focus groups, evaluation protocols, and videotapes of all the MFP sessions. These multiple sources of data allow for triangulation. The course we studied was being taught for the first time by an instructor who had written the course curriculum. The area of mathematics education for parents is so new that research and understanding of how it works and what approaches are most effective are still in very nascent stages. Necessarily, then, our study incorporates goals and approaches found in formative evaluation research as we consider questions of what parents learned and how they learned it. To examine the impact of the course at the cognitive level, we report on two task-based / clinical interviews, one with two mothers (conducted in Spanish) and the other with one mother (conducted in English). The data analysis for the overall research in MAPPS follows Glaser and Strauss (1967) constant comparative method. The different pieces of data are looked at and codified and as conjectures emerge, we go back to the data for affirmation or rejection.

### The Course

Most sessions of the MFP course on Fractions, Decimals and Percents started with a brief activity in which the parents were asked to make connections between the mathematical concept under discussion and their everyday experiences. The rest of each two-hour class involved activities to help parents develop or revisit concepts. About four of the sessions focused on fraction concepts (mostly around the idea of what is a fraction; very little was done on arithmetic with fractions), two sessions centered on decimals, one on percents, and the last one was a wrap-up session in which the ideas about fractions, decimals, and percents were connected. The content goals were primarily on concept development. As a college educated participant explained,

It's not like they give you a book telling you that we're going to learn decimals, start at page one and do a whole bunch of problems about decimals. It's not really about learning how many fractions you can reduce, it's just about starting from the very basic level and developing the concept... it doesn't matter how much math you've learned or how many courses you took in college. Everyone starts at the same point and then we work and develop it together. It's not about just doing the math but understanding why it is the way it is.

Each session included a look at one aspect of the NCTM Principles and Standards as well as a handout with ideas to try at home with their children. In an exit interview, the instructor described her goals for the course as threefold: a) that the parents learn

mathematics; b) that they increase their interaction with their children about mathematics and about school; c) that they have fun. She reiterated these goals often during the sessions and the participants picked up on this,

One the biggest things [the instructor] mentioned, one of her goals was to have fun and see fun in using and doing math. I have really enjoyed it; to me that's really strange because I don't like math. I started with an attitude that I don't like math and this has been a really fun class.

Parents worked in groups, used a variety of hands on materials, and communicated the results of their investigations to the whole class. The activities were largely based on the instructor's collection of activities that she has written over the years and has used in her work with teachers and children. The 23 people who attended the course were women from a working class, largely Hispanic community. The course was conducted bilingually. The parents' mathematical autobiographies as well as comments in the interviews and in informal conversations conveyed an array of largely negative experiences in their prior learning of mathematics. Issues of lack of confidence, of not being good at mathematics, and of feeling alienated were quite common among our participants.

The course pushed parents to revisit "elementary concepts" and in doing so, allowed us to discuss some of the typical difficulties as documented in the literature on rational number, such as the different meanings for fractions, the concept of unit, and the influence of informal knowledge (Lamon, 1999; Mack, 1993). For example, towards the beginning of the course, in an activity with the tangram pieces, some parents quickly said "each piece is  $1/7$ ." Others disagreed and pointed out that the pieces were different sizes. This led to a discussion on the meaning of " $1/7$ " in this context. As the course went on, the participants engaged in contrasting arithmetic/algorithmic approaches with conceptual/manipulative-based approaches to the different tasks proposed. In the next sections we present some of the findings in three areas: affective impact; cognitive impact; and issues related to the parents' interactions with their children about mathematics.

### **Affective Component**

Parents were asked, in small group interviews that were taped and transcribed, to reflect on their learning experiences in the Math For Parents course. A theme that was woven throughout their responses was their recognition that their understanding of mathematics concepts was expanding as a result of their work in the MFP course and the importance that they gave to learning with understanding. A bilingual college educated mother of a preschooler and a first grader, stated:

I always liked math... and.... the formulas... I mean the teacher would give us a formula and I just accepted it, I didn't question I said, okay, this is it, and I applied it. But with these classes we start from the very beginning to see

how they developed... How and why a fraction is a fraction, why a decimal is a decimal. So from the very basic [concepts] ... *and then we have to develop our own formula, that's the biggest thing...* yeah we develop it, and then so when you understand, okay, you can say you know why this is. Because instead of just accepting it, you know it is... Before they would just give us a formula... but now that you understand it you can use it and you'll know how to use it. Developing the concept from the very beginning, starting at the very elementary level and then developing it, that's what I like.

This excerpt is significant in terms of one of our overarching goals for the project which is related to raising parents' awareness about what reform in mathematics education may look like and about what teaching for understanding means. This mother is reflecting on how powerful it is for her to "develop our own formula, ... you know why this is." She also points out how in her previous learning experience, they would just give her the formula and her comments indicate that she does not view this as being particularly powerful. We wonder, will experiencing for herself this kind of teaching that emphasizes meaning make her more likely to expect this for her children's mathematics instruction? Will it make her more likely to focus on helping her child develop meaningful understanding of mathematics concepts?

Parents cited the real-world problem solving activities in their MFP course as contributing to their own understanding of mathematics concepts and they also reported using the real world applications in helping their children make sense of the mathematics they were learning in school:

I liked that she [the instructor] explained what her goals were going to be for the class and then tying the material that we were working with, to real life. Fractions is not just something in a math book it's everywhere.

Some of the projects that we did, you know like going into the newspaper or magazine and finding the percentages, finding decimals, ... So..., in a way that's relevance in the real world where ... you see all these numbers all these fractions, all these decimals, all these percentages... and... you take them in.

You have a lot of relevance in the outside world because you can start to see what you are doing and then apply it. You see it elsewhere, then working with your child, you know now you are in the very basic math level. Then you can also help your children see it somewhere else, that's just not in your math books or math worksheet ... Math can be found everywhere...

Parents also commented on feeling more confident, but showed an awareness that they had just started scratching the surface with this course. In fact, several participants expressed a need for more classes on the course topics:

I feel more confident to teach now.

When I started my confidence was way down. I was ashamed of even being here. But now I even enjoy it, I come because I'm open-minded. I feel better now. I'm not going to say that I learned everything, but I learned a lot.

We were getting into it, and then we changed to something else. We need more time; I hate to say this but maybe more classes.

### **Cognitive Component**

The lessons on fractions focused on concept building. For example, in one activity the participants had to rename each pattern block in terms of what a given one was worth (e.g., if the hexagon is  $\frac{1}{2}$ , then what are the other blocks worth?). In another activity, the participants explored equivalent fractions using color tiles. A few months after the course was over, we conducted two interviews with tasks very similar to the ones the participants had worked on in the course. One interview was with Georgia, who was in her first year of MAPPS. She has three children aged 5, 7, and 13. She is English-speaking and understands Spanish, is a homemaker and completed twelfth grade in Tucson where she studied basic mathematics. She explained that she had enjoyed mathematics in school until the eighth grade when she became ill, missed school and fell behind. When she failed geometry the next year, she found that she just struggled in mathematics and was placed in a basic mathematics course just so she could pass and graduate. The other interview was with two Spanish-speaking mothers, Monica and Elena. They were both schooled in Mexico, where they completed high school. They are both homemakers. Monica's experience with learning mathematics was rather negative while Elena's was overall positive. Monica has two daughters ages 7 and 9, and Elena has a boy age 7 and a daughter age 5.

The interviews revealed a tendency among the three mothers to look for connections between the questions posed to them and everyday life experiences. For example, when asked to give the percent represented by  $\frac{3}{4}$ , Georgia looked at the collection of 4 tiles and said, "Let's pretend this is dollar, so each tile represents 25%, so  $\frac{3}{4}$  is 75% or 75 cents." Elena and Monica were at a loss in many of the school-like tasks. For example, when asked to make a rectangle that was  $\frac{1}{2}$  blue,  $\frac{1}{4}$  green, and  $\frac{1}{4}$  red, they reached for 2 blue tiles, 4 green tiles, and 4 red tiles. Also, throughout the interview it became clear that they were not understanding the questions: they understood the language (the interview was in Spanish), but not the mathematical language. For example, they had a particularly hard time with questions aimed at assessing their concept of equivalent fractions such as in a task where they had said that blue was  $\frac{6}{8}$  and they were then asked, "can you give me another fraction to describe the blue part?" They did not seem to understand what the question was asking.

Georgia also seemed somewhat uncomfortable with expressing herself in a mathematical context, though she was much more successful at solving the interview tasks.

For example, in the task of making a rectangle that is  $\frac{1}{4}$  green,  $\frac{1}{3}$  yellow,  $\frac{1}{6}$  red and the rest blue, her first approach was to take 3 blue, 1 red, 1 yellow, and 1 green. She wanted 6 tiles “because that is the largest number” (and that had worked in a prior task). But she quickly realized that this was not going to work and revisited her work. It took her two more attempts before she came up with a collection that worked. But then she said, “It’s not the biggest number on the bottom, but the number that is times all bottom numbers that give me the number.” So, she seemed to realize a connection to the concept of common denominator. Georgia was quite successful at thinking through the tasks but showed little confidence in her answers. She often turned to the interviewer for validation.

We wonder to what extent these parents would be able to help their children with the typical school-type fraction tasks. But we also wonder how much of their difficulties were related to language, at two levels: the language of mathematics and in the case of the Spanish speaking parents, the fact that the course was taught in English, with Spanish translation. Our classroom observations have raised the question of whether the translations of the English instruction provided effective and equitable learning opportunities for the parents who spoke Spanish. This task-based/clinical interview, in which Spanish-speakers struggled with understanding and expressing their understanding of fraction concepts explored in the course, confirmed our suspicion that the bilingual teaching and learning environment of the math for parents courses needs to be critically examined.

### Interactions with Children

This MFP course was modeled after content taught to children in grades K-6. Parents engaged with the material as adult learners, but one aspect of our research is how what parents learn makes its way into the home. The topics of this course were particularly relevant in that they span over all grade levels and are often perceived as difficult to learn. At this point, what we have is self-reported data in which the parents comment on how these experiences are impacting (or may impact) their interactions with their children. For example, several participants commented that they could now help their children with their homework or at school:

It has helped me to be able to help my children with fractions, in their homework.

Today I worked with one of my daughters, and I learned more in this year with MAPPS. So I’m happy because I can help my daughter with the work. I can understand more if I practice more and more.

This has helped me a lot. Now that I go to my child’s classroom, it’s easier for me to teach them when I sit with them at their table.

Another important aspect that our research shows is the effect that these experiences have on the nature of the interactions between the mothers and the children. It is

not only whether they help them with their homework, but it has more to do with how the children view their parents as a result of their attending classes (Brew, 2001):

And then taking the course helps you reinforce the idea that you're your child's first teacher. We were their first influence, so it empowers us. We are also their teacher and we can help them. They go to school and there's a teacher, and they do their homework and learn. But at home we're their teacher also, then we can help them. They look at us differently.

I have learned ways to interact with my children and also it's fun to have them showing the games to their friends and visitors.

Although these courses are for parents only, some of them occasionally bring their children. Several mothers have commented on the fact that they enjoy sharing their learning with their children, "it's very helpful for the kids to come in and see what they're teaching."

Parents' comments indicate they feel they are gaining both knowledge and confidence regarding mathematical concepts such as fractions that translates directly into confidence in working with their children to understand similar concepts.

### **Conclusion**

Parents' experiences with the teaching and learning of mathematics for understanding are the focus of our study. Others (Lehrer & Shumow, 1997; Peressini, 1998) have shown that the theoretical assertion of the importance of understanding in learning mathematics can be a confusing and controversial one for parents. Our study illustrates an approach that appears to support parents in bridging mathematics pedagogical theory into their own practice of mathematics learning and their own work with their children in mathematics. The parents in the MAPPS program have enthusiastically embraced the idea of the importance of understanding in mathematics; no controversy on this point has been evident.

The study reported here of parents' experiences in a Math for Parents course adds to the small body of literature examining the impact of intervention programs with parents in mathematics (Kliman & Mokros, 2001; Lehrer & Shumow, 1997; Mертens, 1993; Morse, 2001). Our findings suggest that giving parents opportunities to actively construct their own understanding of mathematics concepts provides a critical foundation for their work with their own children. Furthermore, as parents themselves learn mathematics with an emphasis on understanding rather than rote memorization, they become quite vocal about the importance of understanding for their children's mathematics education. As one mother very eloquently said, "I don't want them [teachers] to teach to the test. You have to be versatile in many things. If you don't understand, what's the point?" A key aspect of mathematics reform is the goal to ensure that students understand the mathematics they are learning (rather than memorizing procedures). Yet, this important aspect is beginning to be left behind as the testing pres-

sure increases. In our study, parents reported working with their children to develop mathematical understanding. They talked about incorporating strategies that they had learned in their MFP courses in exploring their children's understanding of concepts in their schoolwork.

This MFP course provided opportunities for parents to engage as adult learners of concepts related to fractions, decimals, and percents. It also provided links to what their children may be doing in school. In a sense there seemed to be several goals for the course, as the instructor captures very insightfully in her reflection,

When teaching children, the goal is mastery as demonstrated on tests and other measures. When working with teachers, the goal is that they understand the material well enough to explain it to students. I felt the goal for the parents was fuzzy. Were they learning fractions, decimals, and percents for their own personal knowledge? Should I have "tested" and "retaught" to make sure they were mastering it? Were they there to get a "glimpse into a classroom of today" and see what learning is like for their children? Were they there to learn enough to be able to assist their children with homework and studying? I know that all of these are goals of MAPPS, but I wonder which one should be the primary one for a MFP course. If the goal is content mastery, then the course probably needs more than eight sessions.

Our findings corroborate that, indeed, in order for parents to be able to help their children with school tasks in these topics, one course like the one we just described is probably not enough for many of the participants. The nature of the interactions about mathematics that these parents developed with their children may be even more relevant and crucial than their actually being able to help them with specific content. Our future plans are for more case studies of parents and their children utilizing both open-ended interviews and task-based clinical interview methods. In addition, a number of questions to guide future research have arisen. How do parents' reported growth in confidence and embracing of reform mathematics pedagogy such as a focus on understanding translate into actual support for their children's understanding in mathematics? How can bilingual instruction for parents in mathematics best be structured to support full participation and learning for Spanish-speaking parents? And finally, what are we learning about appropriate goals and realistic and wide-ranging outcomes for mathematics education programs for parents?

# **CULTURAL INFLUENCES ON TEACHING MATHEMATICS: CASE STUDIES OF INTERNATIONAL TEACHING ASSISTANTS**

Thomas C. DeFranco  
University of Connecticut  
Thomas.DeFranco@uconn.edu

Jean McGivney-Burelle  
University of Connecticut  
Jean.McGivney@uconn.edu

In recent years, teaching assistants (TAs) have assumed a greater role in the teaching of university mathematics courses throughout the United States. As a result, the adequacy of their preparation to teach such courses has come into question. To address this issue, a mathematics pedagogy course was developed and taught and several research studies examining TAs' mathematical beliefs and classroom practices were conducted. Results of these studies indicated that while the TAs appeared to adopt new beliefs about the teaching and learning of mathematics, they perceived several obstacles in trying to employ more reform-minded classroom practices. Further, the background and experiences of international teaching assistants (ITAs) appeared to present unique challenges in their development as teachers. This study, involving four ITAs, was conducted to learn more about the role of culture in the beliefs and teaching practices of ITAs. Data were collected through interviews and observations and analyzed using qualitative methods. Findings, in the form of case studies, revealed aspects of the ITAs' culture that may have impacted their mathematical beliefs and classroom practices.

## **Introduction**

Beginning in 1997 a mathematics pedagogy course was developed and co-taught by education and mathematics faculty at the University of Connecticut to mathematics teaching assistants (TAs). Over the past five years, several research projects have been conducted examining the beliefs and instructional practices of the TAs who participated in the course. Results of these studies indicated that while the TAs appeared to adopt new beliefs about the teaching and learning of mathematics, they perceived several constraints in trying to employ more reform-minded classroom practices. In particular, culture (i.e., individual, departmental, and institutional) served as a lens to examine the barriers the TAs faced in trying to change their instruction. The background and experiences of international teaching assistants (ITAs) have presented unique challenges in their development as teachers. In order to understand this unique group of TAs, a qualitative study of four ITAs was conducted to examine how their past experiences and participation in the day-to-day routines of the mathematics department shaped their beliefs of teaching and learning as well as their instruction.

## **Background of the Study**

Research has indicated that culture plays a significant role in shaping cognition, which in turn influences behavior. Culture refers to the totality of socially transmit-

ted values, beliefs, aesthetic standards, linguistic expression, patterns of thinking, and behavioral norms and styles of expression. ITAs, who are often expected to maintain the norms of U.S. classrooms, exhibit behavior and communication styles that are significantly influenced by their strong cultural orientation (Jenkins, 1997). Further, ITAs often possess beliefs about student-teacher relationships and educational norms that conflict with the educational system in the United States (U.S.), leaving them unprepared to address the different learning styles of U.S. students (Jenkins, 1997; Travers, 1989). Travers (1989) has indicated that ITAs must participate in preparatory courses or seminars to discuss differences in culture and philosophies of instruction if the needs of U.S. undergraduate students are to be met. In order to design such programs and support structures, more research needs to be conducted that examines the nature of ITAs' belief systems and the role of culture in shaping these beliefs.

Research (Olaniran, 1996) on ITAs has identified five variables that influence their teaching performance—including *language, age, academic classification, cultural similarity* and *friendship communication network patterns*. First, due to language concerns, ITAs often resort to teaching techniques that involve lecture-only, memorized presentations. Second, given that different cultures view age and its associated roles and responsibilities differently, ITAs from high power distant countries (i.e., where power and authority are influenced by age) may experience difficulty in U.S. classrooms. Third, teaching assistantships place greater responsibilities, and stress, on ITAs who have to interact with U.S. students (e.g., responding to students' questions or explaining grades received). Fourth, the degree to which an ITA's native culture resembles the host culture may contribute to an ITA's instructional effectiveness. Finally, the lack of host nationals (i.e., in this case, Americans) in ITAs' friendship networks (i.e., circle of friends) may result in teaching behavior characterized by lack of self-disclosure, failure to invite class participation, and cocooning tendencies.

Other research on ITAs has focused on variables affecting intercultural communication, and in particular, the notion of a collectivist versus an individualistic culture (Jenkins, 1997). Collectivist cultures embrace a "strong in-group orientation" centered in relationships with others. In this type of culture, teachers control the classroom, are viewed as the dispenser of knowledge, and don't expect student interaction or participation. In contrast, individualistic cultures emphasize the development of students' individuality of expression and teachers are seen as facilitators rather than fonts of knowledge (Jenkins, 1997). For example, in the Chinese culture, which is collectivist in orientation, "interactions in academia are characterized by a status differential between teacher and student, with higher status accorded to the teacher. Status is maintained by politeness strategies that maintain "positive or negative face" (Jenkins, 1997, p.6). Silence, avoidance, and tentativeness are just a few examples of politeness strategies that may be the preferred and necessary communicative style of a person from a collectivist culture, yet inappropriate and often unnerving for U.S. undergradu-

ate students (Jenkins, 1997). Other research on ITAs has found the transition from a highly selective educational tracking system to an open-admission university is very difficult and ITAs are often unable to identify appropriate levels of instruction, maintain realistic expectations of students, and remain patient when students lack understanding (Damarin & West, 1979).

Beyond these variables specific to ITAs, researchers have long understood that an individual's beliefs about mathematics and the teaching and learning of mathematics play a significant role in shaping characteristic patterns of instructional behavior (Thompson, 1989). Some researchers (Green, 1971) have used the notion of a *belief system* as a metaphor, to describe the organizational structure of beliefs acquired by an individual. In this view, belief systems are dynamic and subject to change (Thompson, 1992) and may help explain certain behavior with respect to teaching and learning. Green (1971) has identified three dimensions of belief systems—a quasi-logical structure, the psychological strength between beliefs, and the clustering nature of beliefs. The quasi-logical structure of a belief system permits beliefs to be “primary” (e.g., a belief that is used as a reason for other beliefs) or “derivative” (e.g., a belief derived from some other belief). The notion of which beliefs are most important, and thereby more resistant to change, has to do with the strength in which these beliefs are held. Psychologically “central”, or “core”, beliefs are held with greatest conviction and are least susceptible to change while “peripherally” held beliefs are more likely to be altered or changed. Finally, the third dimension of the belief system indicates that beliefs are held in “clusters” and generally in isolation from other clusters (Green, 1971). According to Thompson (1992), “This clustering prevents cross-fertilization among clusters of beliefs or confrontations between them, and makes it possible to hold conflicting sets of beliefs. This clustering property may help explain some of the inconsistencies among the beliefs professed by teachers, documented in several studies” (p. 130). In summary, by virtue of participating in the day-to-day routines of family and school life in their native countries, ITAs have been enculturated into the profession of teaching. Further, ITAs' beliefs about teaching and learning are continually shaped through classroom interactions and participation both as a student and teaching assistant in the mathematics department. The purpose of this study was to build on previous research regarding the factors influencing ITAs teaching behavior. In particular, the research question that guided this study was, “What is the role of culture in ITAs' beliefs about the teaching and learning of mathematics?”

### Methods and Procedures

This research project was conducted during the 2001-2002 academic year. Four ITAs, who were participating in the mathematics pedagogy course, were purposively selected to participate in this study. There were two males and two females all of whom were born and raised in different countries (i.e., Kenya, China, Kazakhstan, and Belgium). All participants were teaching two freshmen level mathematics courses

below the calculus and were teaching for the first time in the United States. All subjects participated in four 45-minute semi-structured interviews, which were conducted during the Fall and Spring semesters. The purpose of these interviews was to learn more about their

- (1) early home and school experiences,
- (2) beliefs about mathematics and the teaching and learning mathematics,
- (3) experiences teaching U.S. students,
- (4) perceptions of the culture of the mathematics department, and
- (5) network of people with whom they discussed issues surrounding teaching and learning.

In addition, each subject was videotaped teaching a lesson during the Fall semester and participated in a stimulated recall session. All interviews were audiotaped, transcribed, and coded and these data were organized in a matrix. This information, along with the researchers' field notes, was used to develop four case studies and to identify themes across participants regarding the role of culture in their beliefs on the teaching and learning of mathematics.

## **Results**

### **Blidi**

Blidi\* (all names are pseudonyms) was one of 12 children raised by his parents in a small village in Kenya. Both of his parents earned high school diplomas and valued education. Blidi indicated that age and gender had an influence on one's standing in his community. For example, individuals were expected to show respect for their elders and that if an equally qualified man and woman were to apply for a job, the job would be given to the man. Blidi attended a typical elementary school where the average class size was 50 students. As he entered the middle grades he began preparing for the high stakes national exam to gain admittance to high school. To do this, he remained at school until 6 p.m. and often continued his studies at home for several more hours each night. Blidi attended a prestigious private high school and continued to study and attend classes for approximately 15 hours a day. He described his high school mathematics classes as emphasizing practical applications and places in which students felt comfortable asking and answering questions. He added that if a student didn't understand a topic a committee of students would meet to help him learn the course material. Blidi worked diligently in high school to prepare for the national exam to enter university in Kenya since approximately 50,000 students apply for only 8000 slots at the four main universities. Blidi came to the U.S. to pursue a M.S. in Actuarial Science. At the time of the study, Blidi had been in the United States for three years, and had developed a large circle of U.S. friends whom he met in the classes he was enrolled in at the university.

Blidi indicated that mathematics is a way of understanding the world and should be taught in a more practical and less theoretical way. He commented that he learns mathematics through reading the text and doing examples, but he also regularly visits his professors during office hours to discuss questions he has about the material. Blidi viewed his teaching as an opportunity to educate his students rather than simply as preparation to pass a common mathematics exam.

The classroom observation of Blidi revealed a model of teaching in which instruction was student centered, incorporated both large-and small-group work, and included graphing calculator applications. Acting as a facilitator, Blidi fostered a sense of community in his class by calling on students by name, encouraging student-student dialogue, and circulating around the room throughout the lesson. Further, approximately 90% of his students were in attendance with all students arriving on time and no one leaving early.

Blidi attributed his teaching style to his personality and to the fact that he “understands” U.S. students—that is, they want to participate in class and understand why they need to learn mathematics. He felt very comfortable teaching in English and viewed language, not as an impediment to his teaching but as a tool to engage students in the learning process. For example, Blidi used his misconceptions of the English language to infuse humor in the class, which he believed helped him establish a rapport with his students. He indicated that he routinely reflected on his teaching, reviewed his grade sheet weekly to identify students who may need extra help, and called these students over the weekend to suggest meeting to review the course material.

Throughout the year, Blidi struggled with finding an appropriate way to pace his teaching to meet the demands of the course syllabus and still ensure that students understood the material. He also felt that at times he struggled with maintaining “control” of the class. Blidi appeared to take his teaching responsibility very seriously often planning extensively for lessons that included a mixture of lecture and group work. During the Spring semester, he revised his instruction by trying to encourage more student participation in class. Finally, he indicated that members of the mathematics department, and the chairman in particular, were very supportive of him and helped him improve his teaching.

## Ling

Ling was raised by her parents in a large city in China. Her parents were both college educated and worked in research institutes in China. Ling indicated that in her culture, age had an influence on one’s standing in the community and that individuals demonstrated respect for their elders by not arguing with them. Ling attended a public elementary school and scored well enough on an exam to gain entrance to a boarding school at age 11 where she studied until age 17. According to Ling, the school day was highly structured (e.g., students were scheduled to be either studying, in class, or in the cafeteria between the hours of 6 a.m. and 10:30 p.m.) and the courses prepared

students for the high stakes national exam needed to enter university. Ling indicated that her teachers pushed students to work very hard by assigning many homework problems, testing frequently, and announcing the names of students who scored poorly on quizzes and exams. The general style of instruction was that teachers lectured, students took notes, and there were rare exchanges between teachers and students. Ling did well on the exams and was one of only 15 students in her graduating class of 100 that went on to university. Again, once at university Ling prepared for an exam to enter graduate school and was one out of 6, in a class of 25, which was admitted to graduate school. Ling came to the United States to pursue a M.S. in Actuarial Science. At the time of this study, she had been in the United States for two years. Ling indicated that since in the U.S. she had not made any friends from the U.S. and that she spent most of her time with fellow Chinese graduate students.

Ling indicated the purpose of teaching mathematics is to help students understand the material and to prepare students for the future. Her image of good teaching included being well-prepared, fostering eye contact with students, being organized, writing notes neatly on the board, and providing motivation to learn the material. Ling indicated that she learned mathematics by practicing and solving many problems and studying the textbook.

The classroom observation of Ling revealed a transmission model of teaching, which she described as "a typical lesson". In particular, her instruction was teacher directed and based on a pattern involving the teaching of mathematical theory followed by examples. Her lesson mirrored the textbook presentation of the topic and did not include applications of technology. Ling used the blackboard as the sole means of dispensing information, solicited little to no participation from the students, and with notes in hand, followed a scripted lesson, teaching from the front of the room. Finally, on average, approximately 50% of the students were in attendance with students arriving late and leaving early.

In reflecting on her teaching, Ling believed she had to follow the course syllabus closely since it was well planned by the coordinator who "knew how much time to spend on each topic". In addition, she closely followed the text because she believed her students would understand it better than her. Ling indicated that she modeled her instruction, which is predominantly lecture-style, after teachers in her graduate mathematics courses. She stated that she took her teaching responsibilities very seriously but sometimes was unable to plan sufficiently for class, especially when she was studying for her actuarial exams. Ling believed that the biggest challenge in teaching U.S. students was her difficulty with the English language. In comparing U.S. and Chinese students, Ling indicated that U.S. students "hate" mathematics and do not spend enough time studying while Chinese students do many practice problems and consult reference books when they don't understand a particular topic. She also believed that in China it is the students' responsibility to learn while in the U.S. more responsibility

is placed on the teacher. To improve her teaching Ling consulted her fellow Chinese TAs, her course coordinator, and her husband. For example, when she was wondering how to deal with a student who she perceived was asking “tricky questions that were not relevant to the lesson” her husband advised her to begin class each semester with some very hard problems to show students how smart she was so that students wouldn’t question her ability in class.

During the second semester Ling indicated that her teaching was much improved—she felt more comfortable speaking English and was assigned to teach a higher-level course with brighter and harder working students. However, she indicated that attendance was still a problem and could only encourage the same three or four students to answer questions in class. Finally, she indicated that members of the mathematics department were very supportive in helping to improve her teaching.

### **Olga**

Olga was born and raised in the second largest city in Kazakhstan. Her family consisted of her mother, father, and two older sisters. Both parents were college educated and very supportive of their children’s education. Olga indicated that age and gender influenced one’s standing in her community—that is, individuals would not challenge elders even when they were wrong and generally, men were more respected and had more opportunities than women. Olga attended the best schools in her city from elementary school through high school. She commented that all schools used the same curriculum and class schedules typically consisted of 7 classes a day, each class lasting 45 minutes. Technology (i.e., computers and software) tended to be outdated and rarely used during class. Generally, she spent 2 to 3 hours a night studying and the material was easy to master. Olga commented that teachers were very respected and did not establish a close relationship with students. Mathematics instruction in high school followed a transmission model in which teachers lectured and students listened, with some time reserved for students to ask questions. To enter university, students needed to score well on several exams. Olga stated that professors at university lectured with little student interaction. Student-teacher relationships at university were much more formal than in the U.S. and professors did not hold office hours. Olga indicated that, in her country, “We never blamed the teachers... we think it is our [the students] fault. It doesn’t matter if he is a bad teacher it is our mentality that if you are smart, you will do well, it doesn’t matter how your teachers are. In our country we think students are responsible for learning.” Olga came to the United States to pursue a M.S. in Actuarial Science and at the time of this study, she had been in the United States for two years. She indicated that while living in the U.S. she had not made new friends from the U.S. and that she spent most of her time with students from the former Soviet Union.

Olga stated that mathematics involves the laws of nature and the purpose of teaching mathematics was to help students understand basic problems. She felt that

acquiring mathematical knowledge provides individuals with more opportunities in life. Olga commented that great teachers are kind and make people feel comfortable in class. Further, such teachers get to know their students, respect what they say in class, are flexible, and actively involve them in class discussions. She believed that students learn mathematics by passing the common exams and in one-on-one situations during office hours. To accommodate students' different learning styles she excuses students from class who may already know the material and tells students who are having difficulty to meet her during office hours. In her own learning of mathematics, Olga did homework, attended class, and did what she was told to do in class. It was only at the university that she began to learn how to think about solving problems.

During her classroom observation, Olga relied heavily on her notes and delivered the material in a way that closely mirrored the textbook presentation of the topic. She spent most of the class time writing notes on the board, rarely facing the students. During the period, several students arrived late and left early. Of the students who stayed in class, most sat passively and copied notes. Olga asked a few questions during the period but had a difficult time getting students to answer questions.

Generally, Olga was not satisfied with her teaching performance throughout the Fall semester. She believed that she had little autonomy in her planning and teaching since she had to follow a course syllabus and prepare her students for the common exams. She indicated that she planned between 45 minutes and two hours for each class and that in her planning she thought about examples and how she could explain the material in English to the class. Olga commented that she felt more comfortable using material from the textbook to ensure that it was familiar to her students even though she believed she could explain it more effectively in a different way. To determine whether students understood the material in class, Olga tended to read students' facial expressions. In particular, she looked to one student—when he was happy she believed she was doing well in class. She reflected on her teaching immediately after each class and discussed her teaching with her office mates, husband, and course coordinator. She believed that teaching was the most important aspect of her academic responsibilities since it is embarrassing to her if she didn't do well and because it affected her students and their grades. She indicated that in the future she would like to make fewer mistakes in class, be more confident in her teaching, and be stricter with her students.

Throughout the Fall semester, Olga struggled to balance the demands of her graduate coursework and teaching responsibilities. However, during the Spring semester Olga commented that she felt more confident in her teaching and better understood the expectations of the courses she was teaching. Further, she indicated that while teaching she was more patient with her students, her communication skills had improved, and she relied less on the textbook and more on "her own words" to explain material in class.

## Karl

Karl, an only child, was raised by his parents in a large city in Belgium. His mother attended school until age 11 and his father until age 14. Both parents valued education and expected Karl to earn good grades in school. Karl indicated that the role of age and gender in his country is similar to that in the U.S. His parents paid tuition to send him to a Catholic elementary school and high school since they believed that these schools provided a better education than public education in his city. Mathematics instruction in the schools he attended at this time mainly involved pencil and paper, with little or no integration of technology. Karl indicated that teachers in his country were “information givers” and were the central authority figures in the classroom. Generally, his teachers taught from the front of the class while students remained silent. Although students could raise hands to ask questions, they remained generally passive. Karl mentioned that high school teaching was a well-respected profession but at the university level research is valued over teaching. According to Karl, the university system in his country was “harsh” since in four years students earn what would be equated with a Master’s degree in the U.S. At university, Karl studied approximately 30 hours per week. He came to the United States to pursue a Ph.D. in mathematics and at the time of this study had been in the United States for less than one year. Karl indicated that since in the U.S. he had met people from all different countries and considered himself to be friendly with some people from the U.S.

According to Karl, mathematics is the “queen of the sciences”. He indicated that he decided to study mathematics because of the aesthetic beauty of the discipline. Further, he commented that the purpose of teaching mathematics was to create the next generation of mathematicians and provide students with a sense of its utility. In his view, good teachers are clear, patient, flexible in dealing with different answers, able to say when an answer is correct or incorrect, and able to say in a polite way that an answer is wrong. Further, good teachers are precise, meticulous, and orderly and are able to show the relevance of the topics they are teaching. With respect to his own learning, Karl indicated that he rarely understood lectures and learned by doing exercises alone at home. Further, he said that he learned mathematics by looking at definitions and considering examples and counterexamples. He indicated that he believed students learned mathematics by viewing a solution or by reading the textbook rather than trying to solve problems. He also commented that it was unimportant to concern himself with the different learning styles of students in his classes but it was necessary to recognize when a student was doing poorly.

Throughout his classroom observation, Karl’s instruction modeled a transmission method of teaching. Generally, he taught from the front of the room and students spent the period copying notes in their notebooks. His teaching mirrored a pattern involving mathematical theory followed by concrete examples. He rarely asked for student input—two students asked questions during the period, he addressed them and then

returned to lecturing from the board. Many students arrived late to class and several students left early.

Several times during the Fall semester Karl indicated he was “quite happy” with his teaching performance given that it was his first semester teaching. Upon reflecting on his videotaped lesson, he commented that he felt his English was very clear and was satisfied that he could “read his own writing”. He also believed that he handled students who came in late or were not paying attention appropriately by ignoring them since “learning is the student’s responsibility”. Karl indicated that the model of teaching in his graduate courses is modeled after the Bourbaki-style of teaching and learning (i.e., definition, theorem, proof) and that while he preferred this approach, and tended to teach in this manner, it was not effective with his students. According to Karl, he spent approximately 3 hours planning for every lesson and used the book as a guide. While planning, he spent considerable time thinking about how he could present the material in the book in a better way, how to best say something, which topics should receive emphasis, and how to make connections between chapters or other material in the book. He said that he used humor often in class since he believed it created a personal bond and a rapport with students and “grabbed the attention of someone falling asleep”. Throughout the Fall semester Karl noted differences between students from his native country and students from the U.S. He explained that students in Belgium universities are more disciplined than students in the U.S. He felt that U.S. students spend as much time working (in jobs) as studying and noted that they speak more in class, are sometimes rude, and are not as well prepared for college level mathematics. In reflecting on his teaching, he indicated that he would be “stricter” with students in subsequent classes.

According to Karl, teaching during the Spring semester was easier than the Fall since he was assigned to teach the same course and as a result had less work to prepare. He commented that teaching during the Spring semester was “less work for the same results”. He said that he made some minor changes to his notes, including different examples, and began each class on time. Unlike the other ITAs Karl did not believe there was support in the department to improve his teaching and often felt there was contradictory information given to TAs on how to teach and handle student problems in class.

### **Discussion**

While it is clear there existed cultural differences among all the participants, the data revealed a number of common threads in their backgrounds and experiences. For example, all of the participants had to pass high stakes examinations to continue their education in their native countries and were exposed to models of instruction that involved lecture with little to no student participation. Throughout their schooling they came to view and learn mathematics as an isolated activity—that is, they solved problems independently and read textbooks to understand difficult topics. At

the time of the study, all of the participants were in their first semester of teaching in the U.S. and took their teaching responsibilities seriously. They were expected to follow demanding course syllabi and prepare their students for common exams. In addition, they relied heavily on the course text in planning and teaching the material. All of the participants indicated that models of teaching in graduate school in the U.S. were overwhelming lecture with little student participation. Finally, all participants indicated that teachers in their countries were very respected and they recognized marked differences between U.S. students and students in their respective countries. For example, they indicated that in their native country learning was placed squarely on the shoulders of the students while in the U.S. teachers are expected to shoulder a large part of the responsibility in helping students learn mathematics.

Classroom observations of the participants indicated that Ling, Olga, and Karl employed a transmission model of teaching with little student interaction while Blidi appeared to create a classroom environment where students were actively engaged in learning mathematics. Looking across the cases, what might explain these differences? Differences in the participants' teaching styles may be attributed to cultural variables identified by Olaniran (1996), their academic mathematical preparation, their views about teaching, models of teaching they have been exposed to as students and their enculturation into the mathematics department as researcher and teacher.

The classroom observation of Blidi revealed a model of teaching aligned with a constructivist perspective on teaching. His instruction was student centered and fostered a sense of community by calling on students by name, encouraging student participation, and circulating around the room throughout the lesson. His circle of friends included U.S. students, which may help explain his willingness to create a classroom environment in which students felt comfortable asking and answering questions and participating in class (Olaniran, 1996). Further, just as a strong sense of community permeated his own learning throughout his high school years, he fostered a "community of learners" among students in his own classes. For example, he reviewed his grade sheet weekly to identify students who needed extra help, and called these students over the weekend to suggest meeting to review the course material. Blidi attributed his teaching style to his personality and to the fact that he believed that U.S. students want to participate in class and understand why they need to learn mathematics. He felt very comfortable teaching in English and viewed language not as an impediment to teaching but as a tool to engage and connect with students in class. For example, he used his misconceptions of the English language to establish a rapport with his students.

In contrast, classroom observations of Ling and Olga revealed classroom teaching that would be characterized as teacher directed, with little or no student participation. They each followed a script and students passively took notes from the board. Their instructional behavior can be explained in part by some of the variables identified by Olaniran (1996) that influence ITAs teaching performance—*language, age, and*

*friendship communication network patterns.* Their concern to communicate effectively in English influenced their teaching practice—each resorted to a “lecture-only, and memorized” classroom presentation. Further, both Ling and Olga hailed from high distance power countries where power and authority are influenced by age and in addition, both have maintained close ties with students from their native countries and had no U.S. students in their circle of friends. In addition, in collectivist cultures (e.g., China) a status differential exists between teacher and student and is maintained through “politeness strategies” such as avoidance and silence, resulting in classrooms dominated by teachers with little or no expectation of student participation. Together, these factors provide some justification for classroom instruction in which the teacher is the central authority figure in class (as with Ling and Olga) with little or no student participation (Jenkins, 1997; Olaniran, 1996). Finally, the models of teaching mathematics that both Ling and Olga have been exposed to as students and in graduate school provided a powerful image of a traditional model of teaching and further evidence in explaining their teaching behavior.

Similar to Ling and Olga, Karl exhibited a transmission model of teaching during his classroom observation—he lectured and students quietly took notes from the board. Currently, Karl is studying for his Ph.D. in mathematics and expects to acquire a position as a research mathematician at a university in the future. According to Schoenfeld (1989), “there is a cultural component to learning to think mathematically: Becoming a mathematician involves a process of enculturation, in which initiates become members of, and accept the values of, a particular community” (p. 87). By virtue of being a research institution mathematics faculty at the University of Connecticut direct their energies toward research and mentor graduate students into the process of becoming researchers. Further, anecdotal evidence indicated that most instruction within the mathematics department tends to model a traditional method of teaching—that is, faculty lecture while students take notes, with little opportunity for classroom discourse. Therefore, participation in the day-to-day routines of the mathematics department provides a cultural milieu in which teaching assistants acquire a perspective on mathematics and on the teaching and learning of mathematics closely aligned with a transmission model of teaching. It appeared that Karl has acquired such a perspective on teaching based on his exposure to models of teaching as a mathematics student and his day-to-day interactions with faculty at the university.

### Final Remarks

Research has indicated that culture plays a significant role in shaping cognition, which in turn influences behavior and ultimately one’s teaching performance. In this study, the cultural experiences (e.g., one’s schooling, models of teaching, language, members of the mathematics department, views about teaching, etc.) of the four ITAs have shaped and continue to shape their beliefs about teaching and learning mathematics and as well as their classroom practice. However, there appeared to be varying

levels of consistency between the participants' acquired view of teaching and learning mathematics and their instruction. For example, Blidi appeared to act on his core belief that community plays a central role in educating students and therefore strove to create a sense of community in his classroom. In contrast, while Ling believed the purpose of teaching was to help students understand the material she seemed to act on her core belief that her job was to cover the material and closely follow the textbook and the course coordinator. This is not surprising since individuals can hold conflicting beliefs while acting on their core beliefs (Green, 1971). Further research on the role and impact that core beliefs may have on teaching performance among ITAs needs to be conducted. Finally, the cultural variables outlined by Olaniran (1996) with respect to ITAs and teaching performance seemed to have an impact on their classroom instruction. These variables need further attention. An examination of these variables, with an eye toward improving mathematics pedagogy courses, may lead to an improvement in the teaching performance of ITAs within the mathematics department.

## **SOCIOCULTURAL PERSPECTIVES ON MENTORING MATHEMATICS STUDENT TEACHERS**

Rebekah L. Elliott  
University of Colorado – Boulder  
joriott@earthlink.net

This case study of mentoring in a middle school reform-based mathematics classroom examines learning to teach from a participatory perspective on development. The participants' orientations toward mentoring were considered to capture previous experiences and understandings of the mentor and mentee. In addition, an analysis of the forms of participation and the apprenticeship of the mentee (Rogoff, 1995, 1997) were considered to understand how learning to teach took place on multiple planes of analysis. The study showed that learning to teach was grounded in the mentor and mentee's professional communities. Their guiding orientations of mentoring and forms of participation were influenced by these communities. An implication of the study is that we need to construct mentoring education to include a strong reform-based mathematics content in which normative practices of reflection and collaboration on teaching and learning are second nature to instructional practice. And, mentee education must be coordinated with mentoring education to capitalize on field and teacher education opportunities.

### **Research Problem**

Student teaching is considered by preservice teachers to be one of their most important experiences during teacher education. Undeniably, mentor teachers' actions, beliefs and knowledge play a large role in influencing the nature of this experience for student teachers (McIntyre, Byrd & Foxx, 1996). Research on mentoring documents the importance of mentors' beliefs and provides descriptive accounts of mentor and mentee interactions (Stanulis & Russell, 1998; Hawkey, 1997). However, there are other areas of research such as the context in which student teaching takes place that informs the experience but has typically been ignored by mentoring research (Warren-Little, 1990; Zeichner, 1986). Acknowledging the abundance of research that does not capture both the individual and the environment, Barbara Rogoff (1995, 1997) comments on learning and development in general, explaining that traditional research in these areas have either focused on the individual or the environment. This disconnect effectively limits the researcher's perspective by separating the individual from the environment. This separation of the individual and the environment and the nature of the research on mentoring points to a need for research to coordinate the influence of beliefs, the descriptions of interactions and the impact of the context in a way that acknowledges the interdependence of these influences. This research coordinates these contributing factors to development posing the following research questions. What is the nature of apprenticeship in mentoring activity? What is the nature of guided participation in mentoring activity? And, what is the nature of individuals' influence on mentoring activity?

### Conceptual Framework

This study analyzed mentoring as a sociocultural practice in which learning to teach took place through participation (Rogoff, 1995, 1997). Rogoff's interpretations of sociocultural theory provided a means to examine mentoring as a system of cultural practices, social interactions and individual understanding. More specifically, this system was (1) individuals' understandings or orientations brought to and developed by participation in mentoring, (2) the mentor's and mentee's participation with one another – the forms of participation constructed, and (3) the apprenticeship of student teachers within institutions or pertinent cultural contexts impacting mentoring. Participants' orientations to mentoring were frameworks, developed from past experiences and understandings of learning to teach and mentoring, that guided mentors' and mentees' participation. Rogoff (1995) suggests that development, or the taking on of more responsible roles in activity, takes place through changes in forms of participation. For example, a student teacher learns to teach by learning to taking on more responsibility for classroom teaching and student learning through changes in forms of participation. Apprenticeship in learning to teach is the way that a new member is brought into full membership through the systems of normative practices associated with mentoring learning to teach. To analyze these levels of influence on mentoring and record development I examined individuals' orientations to mentoring, the forms of participation constructed by the mentor and mentee, and how the normative practices of the professional communities to which participants belong were imported into mentoring practice.

### Methods

This study was undertaken within a university reform-based teacher education program. The secondary school selected for the study used reform-based curriculum (Connected Mathematics Project) as the site for learning to teach. The data collected were participant observations of the student teacher, cooperating teacher and other faculty engaged in mentoring practices inside and outside the classroom. All conversations were audio taped and transcribed, including formal initial and final interviews and informal interviews after each cycle of observation. During the informal interviews participants clarified their intentions and understanding of participation. In addition, they provided feedback on my interpretations of events. Participant quotes used in this text are followed by the data source in parentheses. Artifacts from lessons, meetings and emails were also collected. Data were analyzed using external codes based on the conceptual framework for the study and internal codes generated out of the data. Coding checks were conducted by an external researcher to verify consistency and thoroughness of coding. Analytic memos (Strauss, 1987) were constructed for each external code to identify the internal codes or patterns in the data. Vignettes were also constructed to capture the events within the case.

### Findings - Early in the Semester

This paper reports on the data from mentoring a middle school mathematics preservice teacher to illustrate how the coordination of the three planes – cultural, social and individual -- of the conceptual framework provided greater understanding of learning to teach. Ms. Lane, the cooperating teacher, and Ms. Sekwiter, the student teacher, were paired in student teaching because Ms. Sekwiter suggested that she wanted a reform based middle school placement in which she could continue to develop her ideas of teaching in a problem based classroom. Ms. Sekwiter had previous field placements in reform based classrooms and suggested that she was very comfortable with problem-based curricula and student inquiry. Those previous placement were pivotal to Ms. Sekwiter's understanding of learning to teach. She said,

[my teacher] just wanted me to get in there and get going, she just really wanted to see what I could do, what I thought... And it went really well and then she always helped me modify so that it would work even better the second time around (NS, I#1, p. 6).

Ms. Sekwiter's understandings of learning to teach developed from this experience. She thought that she was to try her ideas in student teaching and her mentor would tell her how to modify the "little things of teaching" that she needed to improve. Trying ideas was her orienting framework implying that Ms. Sekwiter was only interested in learning through experience. She comments,

I need the chance to just do everything and try to handle everything all at once. ... how am I going to schedule the things that I need to do and is my perfect theory of what I would like to do going to be able to work ... I think the most important part for me was just I know what I want but can it really work (NS, I#1, p. 8).

As a result of focusing on trying her own ideas, Ms. Sekwiter resisted reflecting on ideas or incorporating Ms. Lane's suggestions into her teaching.

Ms. Lane's orientation to mentoring – reflective practice -- differed dramatically from Ms. Sekwiter's trying ideas. Ms. Lane commented, "... I want to know what they are thinking about, why they would do [something in instruction], tell them that it [is important] to have a reason to do it and they don't just do it without thinking about it" (PL, I#1, p. 33). Reflection was integral to Ms. Lane's ideas of teaching and learning to teach. Ms. Lane attempted to collaborate with Ms. Sekwiter by planning together, asking questions, and co-teaching. Ms. Lane reflected on the nature of these activities early in the semester saying,

... with Nan I don't see her asking as many questions back. So if she comes with an idea and I ask, what about this, what about that, she is already convinced [that her idea is fine], she doesn't modify...[T]hat is what I have seen

so far. So it doesn't have any influence if you ask a question back. I want her to develop so that she understands that teaching, like for me, teaching is not done yet and it is never done, and [for Nan] it is like you want to student teach and then you are done and you know how to teach....(PL, I#1, p. 28).

Ms. Lane thought teaching and learning to teach was a process of developing ideas, questioning the ideas, trying ideas and modifying these ideas through reflecting.

The following is a vignette of Ms. Lane and Ms. Sekwiter's interactions early in student teaching. The vignette highlights Ms. Lane's collaborative efforts and Ms. Sekwiter's responses.

### Vignette

Ms. Lane shows Ms. Sekwiter a pattern problem that she wants students to work with in class. She asks Ms. Sekwiter what they might want students to understand from the problem. Ms. Sekwiter answers quickly, "if they can show a general rule then you know they got it." Ms. Lane asks if there are other ways that students might show that they understand? Ms. Sekwiter appears confused and frustrated that Ms. Lane is not accepting her idea that if the students have a rule then they understand. Ms. Lane discusses the idea that they should allow for other ways for students to show what they know, suggesting that they try the problem in class and see if the students have different solutions. Ms. Lane teaches the lesson and students work in groups while Ms. Sekwiter helps a few groups.

The next day Ms. Lane asks Ms. Sekwiter about what she saw in class the day before and how they might use another pattern problem with the students. Ms. Sekwiter responds that she saw a lot of students not getting an algebraic rule and she guided them in their group to see the rule. Ms. Lane asked if there were other ways that students were seeing the pattern, like did she notice a group of students who described the rule recursively. Ms. Sekwiter sat listening passively. Ms. Lane suggested a way for Ms. Sekwiter to explore alternative solutions in class that day. Ms. Sekwiter never confirmed Ms. Lane's suggestion and added that maybe they could try modeling an algebraic general solution for a pattern to the whole class. Ms. Lane explores what Ms. Sekwiter thinks students will learn from this. She asks if Ms. Sekwiter thinks that they have time during the lesson to do all of this and allow the students to work. Ms. Sekwiter says, "I guess not." Ms. Sekwiter again looks frustrated that Ms. Lane is not acknowledging her idea for the lesson. Ms. Lane asks Ms. Sekwiter to introduce the problem and they both will work with groups during class. Ms. Sekwiter presents the problem without much discussion and begins to work with groups using her idea of showing them a model.

The following day, Ms. Lane has copies of students' work that use different methods to find the pattern. Ms. Lane starts planning by asking questions about the work. Ms. Sekwiter looks frustrated with Ms. Lane and walks away from the table changing

the subject asking about entering grades. Ms. Lane asks Ms. Sekwiter what sense she made out of the students' solutions yesterday. Ms. Sekwiter says from across the room that she thought that most of them got it but some were still not coming up with a rule. Ms. Lane looks frustrated and suggests that they try another problem and that Ms. Sekwiter listen to two groups with different solutions discuss how they saw the patterns. Ms. Lane taught the lesson and Ms. Sekwiter worked again with students. Class ended before Ms. Sekwiter asked two groups to compare solutions.

The final day of working with patterns, Ms. Lane and Ms. Sekwiter start planning for another problem that was more complex than the days before, the triangle problem. Ms. Lane asks, "How are we going to do this?" They each look at the pattern. Ms. Lane asks, "What should they have on their papers that shows that they understand the pattern?" What would we want to hear them discussing? They each worked the math in the problem. Ms. Lane creates different ways that students could find a rule for the figures. She is talking to herself about the various methods students could use and solutions. Ms. Sekwiter has found a solution to the problem and turns to organizing warm ups and worksheets that need to be copied for the day. Ms. Lane has her solution notes in front of Ms. Sekwiter working on them. Ms. Sekwiter walks away to go make a stack of copies near the door and find the attendance book

Ms. Lane looks up at Ms. Sekwiter and asks her, "What would be the a way to support students getting into the problem?" Ms. Sekwiter sits back down and says,

### The Triangle Problem

Figure 1 

Figure 2 

Figure 3 

Figure 4 

Given that the length of each side of the triangle in figure 1 is (1) unit

- Find the # of triangles, # of rows and perimeter of each figure
- Find the rule for the # of triangles and perimeter of the  $n^{\text{th}}$  figure.

Figure 1. The Triangle Problem.

"Well we could draw a chart and then have them follow us filling in the chart to find the patterns for each piece. And we could find one rule for them." Ms. Lane replies, "What do you think some of them will understand about the numbers in the chart?" Ms. Sekwiter says she is not sure, but, "I just think that if we show them one of the rules then they can follow what we have done and find the other rules." Ms. Sekwiter continues to elaborate on her idea that they should show the students a chart to organize their work. Ms. Sekwiter says that she thought about this all the way home yesterday, that a chart was what the students needed to see patterns more clearly. After three days of asking Ms. Sekwiter about making sense of students' solutions and Ms. Sekwiter suggesting ideas for teaching the lesson, Ms. Lane has reached a dead end with posing questions to foster reflection and assessment of students' thinking – Ms. Sekwiter is unwilling to modify her idea. Ms. Lane suggests to Ms. Sekwiter that she teach the pattern problem based on her idea of the chart.

Ms. Sekwiter teaches the lesson and Ms. Lane observes from her desk. Some students have trouble creating the chart and don't understand where Ms. Sekwiter is finding the numbers for each of the columns.

They ask questions and Ms. Sekwiter suggests they aren't paying attention. Ms. Sekwiter is working out each step of the chart. Some students have solved the problem

| Ms. Sekwiter's Chart   |               |                    |                  |

and are discussing their different solutions while Ms. Sekwiter is working at the front of the class with the chart. Class ends before Ms. Sekwiter models finding a rule.

Ms. Lane asks Ms. Sekwiter, "How do you think it went?" Ms. Sekwiter responds, "Well it didn't go too badly. Those that needed the chart at least saw how to organize their work." She adds, the class had quite a few students who had been absent so those students lacked experience with patterns. Ms. Lane asked Ms. Sekwiter what one student was thinking when he asked "look the numbers are growing from one step to the next." Ms. Sekwiter said that she saw that he was basing the pattern on the previous number but she wanted to get to general rule. She added that the student that brought that up was also not paying attention during most of her discussion. Ms. Lane asked Ms. Sekwiter about running out of time and how she might modify the lesson. Ms. Lane suggested that she didn't realize she had run out of time until there was only three minutes left. Adding, that the clock in the room was difficult to see since it was at the front of the class. Ms. Sekwiter suggested that the students in the afternoon class were not as easily distracted so it would probably go better the next time.

Ms. Sekwiter had difficulty making sense of lesson and knowing how she could modified the lesson to address the issues. Ms. Lane said that she would teach part of the afternoon lesson and that Ms. Sekwiter could watch how she worked with the pattern problem.

### Patterns of Interaction

Early in the semester Ms. Lane worked with Ms. Sekwiter on developing, questioning, and modifying ideas through reflection. Ms. Lane was attempting to build Ms. Sekwiter's content and pedagogical content knowledge through reflection on experience. Reflection focused on mathematical ideas, students' conceptions, and formative assessment of student discourse and written work. This reflective process was difficult for both Ms. Lane and Ms. Sekwiter. Ms. Lane had created a form of participation in mentoring in which she attempted to engage in meaningful conversation, yet Ms. Sekwiter was focused on trying ideas. Mentoring early in the semester developed into a pattern of miscommunication, in which both Ms. Sekwiter and Ms. Lane communicated their ideas of how to participate in mentoring without the other listening.

The participants' orientations to mentoring learning to teach framed how they participated in mentoring events and the resulting miscommunication. Ms. Sekwiter's trying ideas orientation guided her to pursue ideas and gain experience teaching. Her orientation did not include deep reflection on ideas. This orientation was built on Ms. Sekwiter's previous field experiences from which she came to understand learning to teach as gaining experiences and a mentor's job was to tell her how to improve on her teaching strategies. Contributing to Ms. Sekwiter's guiding orientation was her understanding of the work of teaching. For Ms. Sekwiter teaching was about collecting interesting and fun activities that engaged students in doing math. However, she was not clear on what the important mathematical ideas were and how she would make the

math explicit in her fun activities. Ms. Sekwiter gathered these activities from teacher friends, searching the internet and teacher resource workbooks. Most prominent in her discussions of these resources was Ms. Sekwiter's associations with teachers that would share activities with her to try during student teaching. Ms. Sekwiter was creating her bag of tricks by gathering activities from other teachers.

Ms. Lane believed the collaboration was at the heart of mentoring learning to teach early in the experience. Ms. Lane's reflective orientation to mentoring framed how she understood the job of learning to teach and her role in that process. In-depth conversations about teaching, learning and mathematics were essential to developing as a teacher. Ms. Lane was a long-standing member and leader in reform-based professional development. She suggested that she based her understanding of learning to teach on these experiences, importing the purpose of mentoring learning to teach from this professional community.

As the semester progressed Ms. Lane became more frustrated with Ms. Sekwiter's lack of reflection and willingness to question and modify her ideas. Ms. Lane came to understand that Ms. Sekwiter was not able to see all the complexity of teaching while they were collaboratively teaching. She commented that Ms. Sekwiter was "not open to learning" anything more from sharing the responsibility for teaching. As a result, Ms. Lane shifted how she and Ms. Sekwiter participated in mentoring. Ms. Lane suggested that Ms. Sekwiter begin her solo teaching time in which Ms. Sekwiter would be responsible for all the teaching.

### **Findings - During Solo Teaching**

Even though Ms. Sekwiter expressed that she saw her placement as "fitting right in with [her] previous placements" her orientation of trying her ideas, conflicted with Ms. Lane's orientation of reflection and discussion that framed her participation in mentoring. The differing orientations precluded Ms. Sekwiter from engaging in reflective discussion with Ms. Lane. Ms. Lane's process for collaboratively teaching was not understood by Ms. Sekwiter as an appropriate means of engaging in mentoring. Ms. Lane struggled to understand Ms. Sekwiter's ways of engaging in mentoring. About a month into the semester Ms. Lane suggested that she would have to "figure out" how to work with Ms. Sekwiter. Prior to soloing, her process for figuring this out included trying a variety of methods to engage in reflection, each garnering only limited success.

Soloing proved to be a vehicle for Ms. Sekwiter and Ms. Lane to begin to discuss the complexities of teaching reform-based mathematics. After a number of unsuccessful teaching episodes in which Ms. Sekwiter was baffled by students' behavior, Ms. Sekwiter began to reflect, ask questions and examine her practice with the guidance of Ms. Lane. The change in participation – soloing-- facilitated by Ms. Lane, was a catalyst for Ms. Sekwiter's development in learning to teach. In addition, Ms. Sekwiter reviewed the text and surmised that she did not know how to facilitate the

mathematical ideas suggested in the teacher's notes. She came to Ms. Lane with questions, asking for help. This was a shift in their ways of participating in mentoring. Ms. Sekwiter began to develop new ways of communicating about teaching. She began to look deeper and reflect on her instruction.

### Analysis

The forms of participation that constituted mentoring practices early in the semester did not provide for Ms. Sekwiter to try her ideas to the full extent that she believed was appropriate. These forms of participation were constructed by Ms. Lane, with the intention of incorporating Ms. Sekwiter's ideas, but these opportunities were less than successful. Ms. Lane thought that Ms. Sekwiter's lack of reflection constrained their collaboration and Ms. Sekwiter's learning to teach. Ms. Sekwiter thought that Ms. Lane's need for reflective discussion on ideas was not part of her job as a mentee and simply was Ms. Lane controlling her access to trying her ideas. The participants' guiding orientations framed how they participated in mentoring. The forms of participation did not facilitate development in learning to teach until Ms. Lane shifted the nature of the work. Consequently, Ms. Lane backed away from her attempts to make Ms. Sekwiter engage in reflection *prior to* taking full responsibility for teaching and suggested that she start her solo teaching time. This shift in participation was a marker of development in the case.

Development in learning to teach in this study was examined on three planes of analysis. On the individual plane, participants' orientations were the unit of analysis which uncovered how participation in mentoring was guided by the mentor and mentee's experiences and understandings of mentoring learning to teach. These guiding frameworks informed how participants engaged in mentoring interactions. On the second plane of analysis, forms of participation constituting mentoring were examined for shifts in participation that marked development of the participants. On the third plane of analysis, the nature of the apprenticeship was examined to understand how mentoring was a sociocultural practice. Apprenticeship, "focuses on the *system* of interpersonal involvements and arrangements in which people engage in culturally organized activity." (Rogoff, 1995, p. 143) The emphasis on this plane is not the actions of the participants, but the ways these actions are bound by normative practices of the larger institutional or cultural context.

Wertsch, Minick and Arns (1984) suggest that to understand individuals' actions when engaged in activity we must look to the sociocultural context in which the activity is situated. Participants import ways of acting from these familiar settings to guide participation in other cultural activity. In this mentoring case the other cultural activities that related to mentoring were the professional communities in which Ms. Lane was a member and that Ms. Sekwiter had associated with prior to and outside of student teaching. These were different communities that had different normative practices.

Ms. Lane imported the reflection, discussion and content she engaged in while attending and leading reform-oriented mathematics professional development. Ms. Lane participated in two long-term professional development projects during the year of the study, devoted to mentoring and reform-based teaching. These opportunities were formative to her mentoring of Ms. Sekwiter. She suggested that her purpose for mentoring was to facilitate a student teacher's entrance into the profession by adopting the normative practices of the reform-based community. For example, Ms. Lane's discussion of students' conceptions, mathematical big ideas and formative assessment were topics in her professional development experiences as well as embedded in her instructional practices. Her experience of reflecting on these topics in professional development permeated what she understood as important to learn during student teaching. Furthermore, Ms. Lane was being mentored during this semester of observations by an experienced reform-based teacher that she respected. Ms. Lane capitalized on this experience by reflecting and incorporating into her mentoring of Ms. Sekwiter what and how she discussed teaching and learning with her mentor. These professional development opportunities were Ms. Lane's more familiar activity settings that informed her purpose for mentoring and her interactions.

Ms. Sekwiter's imported the ways of interacting that she had developed in her early field experiences and what she understood to be important to teaching gained through conversations with teacher associates. Each of these contexts provided Ms. Sekwiter with evidence that teaching was about gaining experience and trying different ideas. She commented that she did not witness her previous mentor needing to reflect on their experiences nor engage in a process of discussion and modification. Ms. Sekwiter's orientation to mentoring and her participation were guided by the normative ways of thinking and acting that she witnessed in previous teaching experiences and associations with teachers.

### **Implications**

Ms. Lane's purpose for participation in mentoring, the forms of participation constructed and her orientation to mentoring, was commendable and embodied many of the suggested best practices of mentoring (Peterson & Williams, 1998). The content of her mentoring focused on learning to teach reform-based mathematics using notions of professional skills such as reflection that are central in the NCTM Principles and Standards. However, when examining the outcomes of the mentoring interactions Ms. Lane's orientation and forms of participation were less than fruitful. Ms. Sekwiter's focus on trying her ideas was typical of student teachers, but it did not facilitate reflection on her practice (Borko & Mayfield, 1995; Elliott & Calderhead, 1993). What guided these the participants' orientations to mentoring and the ways of participating were the participants' membership in professional community and previous experience with the profession. The differences observed between the mentor and mentee were not merely individuals' different perceptions, rather they were the participants'

familiar activity settings that served to orient their mentoring activity (Wertsch, Minnick, & Arns, 1984).

The data in this paper illustrated how the cultural practices of professional communities impacted the social interactions and individual orientations that inform mentoring activity. This research coordinated the individual, social and cultural influences on learning to teach by examining development in sociocultural activity. One implication of the work suggests that mentors and mentees need support to develop cohesive orientations to mentoring. In addition, mentor education, long reported as important for developing strong mentors, proved to be important to the content of mentoring (Feiman-Nemser, Parker & Zeichner, 1993). However, the nature of mentor education has been broadened by this study to include the professional development focused on reform-based mathematics. Furthermore, mentee education must also be included in the call for support of mentoring activity. There is a need to leverage the learning opportunities in student teaching and previous field experiences coordinated with the theoretical perspectives represented in teacher education to develop sound mentee education.

# **WOMEN, MATHEMATICS, AND SOCIAL RESPONSIBILITY: THE ROLE OF WISDOM IN CHOOSING A COLLEGE MAJOR**

Judith Lynn Gieger  
Oglethorpe University  
lynngieger@yahoo.com

This study addressed the question of what factors impact mathematically talented college women's choice of academic major. Twelve participants engaged in a 12-week on-line bulletin board discussion group, and the data were collected and analyzed using the qualitative method of constant comparative analysis. This study found that four central factors influenced choice of major among these participants: environment, behavior, talent, and value. Value had the highest relative influence, as these women were deeply concerned about the positive social impact of their future careers. Many participants had conflicts with the perceived values of the mathematics departments at their colleges and universities, and those conflicts were often cited as the central reason (and occasionally the only reason) that a participant was not majoring in mathematics. This paper also discusses how university mathematics departments can use these findings to address the problem of female underrepresentation in undergraduate mathematics programs.

## **Purpose and Background**

The purpose of this study was to examine how mathematically talented college women come to decisions concerning their academic careers. This study focused primarily on the decision of college major. While a large body of research already exists on this topic, previous research studies concerning mathematically talented girls and their academic plans have focused almost exclusively on the differences between mathematically talented girls and boys (Eccles, 1985, 1989). Because previous research has indicated that mathematically talented boys have been more persistent and more successful than mathematically talented girls, the often unstated question being asked in many of these studies addresses the ways in which girls can be changed to be more like boys (Benbow & Lubinski, 1993; Cramer & Oshima, 1992; Heller & Ziegler, 1996). This approach does not necessarily shed any light on the potentially unique issues that talented women in mathematics find to be important in their decision of a college major. Therefore the results cannot necessarily be used to determine how college and university mathematics departments might attract talented women to their programs. A greater understanding of how mathematically talented women make the decisions that they do requires a study of the women themselves rather than a comparison of them with men.

## **Methodology and Data Sources**

The participants in this study were 12 mathematically talented college women from various colleges and universities throughout the United States. I gained access to

the participants through the use of a network selection process called *snowball sampling* (Patton, 1990, p. 176). A small initial group of potential participants forwarded a proposal to other mathematically talented college women (at their own university and others) who they thought might be interested in participating. Each new potential participant also passed on the names of a few interested individuals, which resulted in a network of 24 potential participants. Using biographical questionnaires, I selected 12 women who as a group represented a wide range of colleges, ages, and majors and individually best met the essential criterion of exceptional mathematical experience, looking particularly for a balance between traditional measures of mathematical ability and interest in mathematical activities. All participants also met the criteria of having a declared major, although only 4 of the 12 were majoring in mathematics.

The participants engaged in a 12-week on-line bulletin board discussion group, moderated by the researcher, in which they discussed the variety of issues that had influenced their choice of whether or not to major in mathematics in college. In order to keep the group size and reading load for the participants manageable, I assigned the participants to two separate bulletin boards (6 members each) operating simultaneously. This decision also allowed for the possibility that topics and lines of conversation might arise in the two groups independently, adding strength to the finding that such an issue was essential and important to the participants' choices. Assignment to the two groups was not random but purposeful (Patton, 1990). I wanted to have two groups that were as diverse as possible in age, college affiliation, and major. Because of the nature of the network selection process, several participants knew each other well and might possibly have recognized their friends despite the use of pseudonyms. Therefore, some participants were placed in separate groups to protect their anonymity. Each participant was able to access only the discussion board for her assigned group. In addition to all electronically collected data from the two discussion groups, the women also participated in an individual interview, either in person or over the telephone, at the conclusion of the on-line portion of the study.

The process of data analysis in this study followed the traditional format applied in grounded theory research: constant comparative analysis (Corbin & Strauss, 1990; Creswell, 1998; Glaser, 1992; Glaser & Strauss, 1967). An essential component of the constant comparative analysis method is that data collection and data analysis are interrelated, often simultaneous, events. This method of data collection and data analysis allows for categories and related questions to emerge from the data, at which point these questions are taken back to the participants for further discussion. These categories and questions arise primarily during the initial open coding process. Categories are developed, discussed, and explored in an iterative fashion (gather data from participants, analyze the data, return to the participants for more data, etc.) until the categories are "saturated." One way in which this level of analysis was employed was through summaries posted to the bulletin board by the researcher. Participants

could respond to and amend these summaries throughout the 12-week bulletin board discussion period. This method of ongoing responsive data analysis also helped guide the formation of questions for the closing interview.

According to the techniques of grounded theory, additional levels of coding and theorizing take place after the initial open coding process. I used axial coding to take the initial categories from the open coding phase and assemble them in a logical fashion. The purpose of this stage of analysis was to identify a central phenomenon and to explore causal conditions, strategies, and intervening conditions that affected it. I was initially influenced by previous models used to describe this phenomenon, such as Eccles (1985, 1989) model of choice, but I soon found that previous models were not adequately describing the conditions and factors that affected the participants' choices. In particular, these models did not account for the fact that while many factors affected the participants' choices, not all of these factors carried the same weight in the decision process. Simply put, some factors were more important than others. For example, the code *positive social impact in career* (which related to value) had a much stronger quantitative and qualitative grounding than the code *grades* (which related to expectancy), and the organization of the codes into categories needed to reflect this finding.

After axial coding, I used selective coding to integrate the categories that emerged from the axial coding into a "story line" that would outline a conditional proposition or theory. I assembled four core categories and their subcategories into a model that described the relative importance of a variety of factors that influenced the participants' choices about their majors. Some of the initial codes were combined and others abandoned, but this decision was made based on the need to include only the factors that the participants claimed influenced their choice of majors. The four central categories and their subcategories therefore represent the result of the collapsing, combining, and elimination of codes throughout the analysis process. Although the labeling of the central factors was my own (as a result of the analysis) and not a direct phrasing by the participants, the data supported the use of the terms.

### Findings

On the first day of online data collection, I posted a question to both groups concerning the participants' beliefs about their mathematical talents. I had the idea that their beliefs about their mathematical talents would have had a large impact on whether they chose to major in mathematics or not major in mathematics. I was quite surprised when, on the same day, one of the participants, Elizabeth, posted the following entry:

*I think in the overall scheme of things, talent is not the most important thing.  
Talent is secondary to passion.*

The other members of the discussion group strongly echoed and supported her sentiment. Surprisingly, a similar sentiment arose in the other discussion group, inde-

pendent of Elizabeth's comment. It was almost as if the participants were saying to me, here's what's really important to us. They continued to explore this idea of passion throughout the entire 12-week online discussion, gradually elaborating on what they meant by *passion*. Passion was not simply enjoyment of a subject (although that was certainly a part of it), but it was more the sense that what they were doing had purpose and value. Any theoretical representation of the factors that influenced the participants' choices of majors would have to focus on this sense of purpose and value that was at the core of their decision processes.

It was soon obvious, however, that value alone was not sufficient to describe why these women had made their choices. Note that, in the above quote, the participant claimed that talent was secondary to passion and not that talent was irrelevant. Talent was necessary in order to be successful, but that success was considered less valid if it did not match a participant's sense of values. The online discussion was peppered throughout with other factors that influenced the participants' choices of majors, but each of these factors was discussed in a way that showed how they culminated in a need for value and worth. This sense of relative and culminating importance led to the development of the model of academic choice.

Regardless of major, the women in this study made choices about their major based on four domains: environment, behavior, talent, and value. These domains are listed in order of relative importance, from least important (environment) to most important (value). Although the relative importance of these domains does not necessarily reflect the order in which the participants addressed the issues present in the domains, the culmination of the four domains can be demonstrated by the following sequence of questions:

- How comfortable am I in the environment of my major department?
- What kind of behavior is expected in the department in order to be successful?
- Do I have the necessary talent to be successful in the department?
- Do I believe those talents and behaviors are valuable for me to cultivate?

This sequence of questions, and the relative importance of the domains that they represent, illustrates the model of academic choice arising from the data. This model does not assume that the student will necessarily reach a total agreement between the four domains, as new information and experiences will cause the student to constantly reevaluate and reexamine her choices. It is unlikely, therefore, that a student would ever reach a point in her decision process when she experiences no internal conflict whatsoever with the academic choices that she has made, and the data from the participants in this study supported the perspective of academic choice as a dynamic set of experiences rather than a single discrete event. The relative importance, however, of these domains does reflect the likelihood that a conflict would cause a participant

to change her major. When a conflict was experienced at any level, the participant resolved this conflict by either reaching a compromise within the self about her current major or by changing her major outright. A conflict in the environment domain often resulted in an internal compromise which did not cause the participant to leave her department, whereas a conflict in the value domain often resulted in the more dramatic decision to change majors. It was therefore essential to the participants that they experience little if any conflict with the values of their major departments, as a conflict in this domain most likely resulted in their leaving the department.

The findings for the general model of choice are consistent across participants when applied to the particular decision of whether to major in mathematics or not. The participants cited few if any conflicts with the environment of the mathematics departments at their colleges and universities, and this domain had relatively low importance in their decision of whether or not to major in mathematics. On the other hand, many participants had conflicts with the perceived values of the mathematics departments at their colleges and universities, and those conflicts were often cited as the central reason (and occasionally the only reason) that a participant was not majoring in mathematics. Therefore, the domain of values held a relatively high level of importance in the participants' choices of whether or not to major in mathematics. Also, all participants who were majoring in mathematics claimed that they found their majors satisfying in the value domain, confirming the general finding that satisfaction in the value domain was essential to a participant's overall satisfaction with her choice of major.

Given that all of the women in this study had considered (albeit a very brief consideration for some) mathematics as an option for a major, they were particularly qualified to speak about how their experiences with mathematics and mathematics departments and classes affected their choice of major. It is particularly interesting that the large majority of the participants expressed little conflict with their mathematics departments in the first three domains of the model. In general, they found the environment to be hospitable, the activities and behaviors to be purposeful and enjoyable, and their talents to be more than sufficient to be successful. As noted above, the largest source of conflict for the participants lay in the domain of values, where they began to question if the environment, behaviors, and talent that they possessed fit in to their larger system of what they believe is important about their role in the world. These women expressed great concern that they use their talents not just for their own enjoyment, but also for the larger good of society as a whole, as the following quotations demonstrate:

Jane: *I would like for my job to involve cool people and be intellectually challenging and interesting, but ideally I'd like to think it was worthwhile too. . . . What I learn is never as important to me as personal relationships and helping people in some way. What I study is just the means for attaining that goal.*

Elizabeth: *I had to write an essay for college about why I wanted to study math. I didn't [want to study it]. It was a game...a game I was good at, but merely a game...for me at least. It was just puzzles, and oh, this is fun. But then to say that I'm going to make this my life? I don't believe that I want to spend the rest of my life doing something that's not going to help people.*

Esther: *I don't think I could feel good about succeeding in my field if I couldn't see it in some sort of wider context. I've said this a lot, but some concrete result, which has a tangible impact on the people around me, has become important. And hopefully I'll make a positive impact in my career. It's all about people, right?*

Hadley: *Whether or not people acknowledge it, I think everything and everyone has some sort of social impact, and so for me, it makes more sense to strive to have a positive one.*

To this end, it was important to the participants' sense of values that their majors, and subsequent career choices, encompass the goal of social responsibility.

This finding aligns with theories of talent as the application of knowledge and can be used to discuss how a person might make use of his or her mathematical talent. These characteristics are sometimes referred to as *evaluative skills* (Bloom, 1985), and they provide a link between the development of talent and the appropriate use of that talent. Sternberg (2000) refers to this perspective as *wisdom*, which he defines as "the application of tacit knowledge as mediated by values toward the goal of achieving a common good" (p. 253). This goal is achieved by balancing multiple interests (intrapersonal, interpersonal, and extrapersonal) among responses to environmental contexts. The perspective of talent as knowledge application does not eliminate the need to discuss the development of mathematical talent in terms of practical, analytical, and creative talent, but it places a goal of the common good and social responsibility as central to the individual's need and desire to develop his or her mathematical talent in these ways. In short, wisdom involves not only intelligence, talent and creativity, but also concern for others, judgement, intuition about right and truth, and the sense that knowledge is not value-free (Csikszentmihalyi & Rathunde, 1990; Sternberg, 1990, 2001). Unfortunately, the large majority of participants did not find the idea of a career in mathematics to satisfy their need for social responsibility, and therefore they chose other majors and careers in which they felt that they could better utilize these components of wisdom.

### Conclusions

The results of this study draw attention to the importance that values have played in mathematically talented women's academic decisions. These findings demonstrate a level of concern deeper than the one addressed by the common practice of attempting

to draw talented women into mathematics departments by making the environment more female-friendly (Hanson, 1996; Henrion, 1997). A congenial, supportive environment certainly played a role in these women's decisions. However, the findings indicate that research on women in mathematics that focuses almost exclusively on the environment may be misplacing its efforts. Rather, this research points toward a practice of drawing women to college and university mathematics departments by addressing all domains of the choice model, with particular emphasis on whether the program addresses the individual's sense of values.

How might undergraduate mathematics departments use the findings of this study indicating that values are the most important factor in talented women's decision whether or not to major in mathematics? Much of the decision rests with the impressions that students form of the values of a mathematics department in the first years of undergraduate study. If a student does not have the impression within the first two years of college that a major will be satisfactory in the value domain, then she is unlikely to make that major her final choice. Considering that many of the participants viewed the first year of college mathematics as consisting of "weed-out" survey courses, it is not surprising that very few saw an undergraduate major in mathematics as an attractive option. They were already concerned about the relevance and social implications of their academic work, and their early mathematics courses provided few indications that mathematics met these concerns. Instead, these courses, as well as many subsequent courses, focused almost entirely on proofs rather than relevant applications.

These findings are similar to those of a recent study of female undergraduate computer science majors at Carnegie Mellon University (Margolis & Fisher, 2002). The researchers found that female students were drawn to computer science because of what they perceived as the positive social implications of computing innovations, yet their experiences in their early computer science courses focused almost exclusively on programming. As a result of these findings, Carnegie Mellon made serious changes in the structure and curriculum of their undergraduate program in computer science. One of the changes put in place was the institution of an "immigration course" (IC) for students entering the undergraduate program. Previously offered only to incoming doctoral students, this course was designed to provide students with a broader, contextualized view of the field than they tended to receive in their early programming-oriented courses. As a result of the new course, freshman and sophomore computer science majors who had participated in IC had a much clearer view of the field and its applications than students who had not had the opportunity to participate in IC. As a result of this change as well as many others (including student recruitment efforts and increased focus on quality teaching), the proportion of women entering Carnegie Mellon's undergraduate computer science program rose from 7 percent in 1995 to 42 percent in 2000. This dramatic change in the proportion of women in a depart-

ment speaks to the power of early efforts to place undergraduate coursework within a broader context.

The findings of this present study support the idea that undergraduate mathematics departments could also benefit from instituting such an "immigration" opportunity for their students that focuses on the social implication and value of mathematical work. Although it is true that undergraduate mathematics departments have to some degree always addressed the issue of the value of mathematical study, much of their emphasis is on the aesthetic value of the subject—the inherent beauty of mathematics and the pursuit of knowledge for knowledge's sake. This aesthetic value was certainly important to the women in this study, as they were unlikely to pursue a field that they did not find enjoyable on a personal, intellectual level. However, equally if not more important to these women was the value of their work in context. How was their work going to affect the work of others? If the culture in their major departments was not able to provide an answer to this question, then they were less likely to remain in that department. This view challenges undergraduate mathematics departments to place early emphasis on not only the intellectual value of mathematical study but its social value as well.

# **DEVELOPING MATHEMATICAL IDENTITY: A LOOK AT A TWELFTH GRADE MATHEMATICS CLASSROOM AS A COMMUNITY OF PRACTICE**

Kara Jackson  
University of Pennsylvania  
karajack@dolphin.upenn.edu

Using a socio-cultural lens, this paper employs a community of practice framework (Lave & Wenger, 1991) to examine the mathematical identity formation of a group of twelfth Grade 12 in an urban Discrete Mathematics classroom. Within this community, the individuals re-negotiated their mathematical identities as they participated in the practices of the classroom. In this classroom, it appears that (1) the majority of the students developed their own mathematical identities in relation to the valorized practices (de Abreu, 2002) of this particular classroom, and thus articulated such positive development when they engaged in such practices, (2) the practices of this classroom did not occur in isolation from other social and institutional practices, and (3) students positioned themselves and others with respect to valorized and sometimes contradictory practices.

While being in this urban Discrete Mathematics classroom, I became aware that this classroom was one where the teacher and regularly attending students co-created a community in which three interrelated practices were valorized: working collaboratively in groups, students' and teacher's sharing of knowledge, and clear explanations of mathematical processes. The majority of students engaged fully in these practices, and as a result, articulated changes in what I call their mathematical identities. Although there were certainly limitations to what the teacher and students were able to accomplish, in this paper I seek to understand the processes that contributed to these students' positive development of mathematical selves. However, there were also contradictory practices within this classroom that sometimes made negotiation of one's participation difficult. I also seek to understand the choices students made in their participation, and how these choices affected their positioning in the classroom.

## **Methods and Data Sources**

This paper presents an ethnographic study of a semester long Discrete Mathematics classroom in an urban high school. Within this high school of 1800 students, almost 99% were African American and 86% were from low-income families. This 12th grade Discrete Mathematics class was in the Business Small Learning Community (SLC)<sup>1</sup> of the high school.

This class was taught by Ms. Lorraine Smith<sup>2</sup>, an African American veteran math teacher of 27 years. She had taught in this particular school for 12 years, and was responsible for much of the secondary mathematics curricular reforms in this urban district. In this class, there were 40 registered students, but on the days I observed, an

average of 25 students were present. Of these 25 students, there were on average 15 females and 10 males. All students identified themselves as African American, with the exception of two females who came to the United States in the fall of 2001 from Sierra Leone. The desks in the classroom were arranged such that four desks were pushed together to make a table. Students chose their own seats around a table with three other students. The majority of the students grouped themselves according to sex.

At the time of this study, there was no district-wide curriculum for "Discrete Mathematics." Thus, Ms. Smith composed the curriculum on a daily basis. She defined Discrete Mathematics in this context as "problems that take days to solve" and found problems from the World Wide Web and other math books. Typically, the mathematical projects took three or four days to complete. For example, the class began the year by examining patterns that could be solved with combinatorics; students were urged to solve these problems without using formulae, but instead by conceptually mapping the problems, finding rules, and using these rules to generalize to solve subsequent problems.

My data included detailed field notes from over 50 hours of classroom observation, informal conversations with the teacher and students, 30 student surveys, a 50-minute teacher interview, and 21 student interviews, each averaging 8 minutes. Analyses for this paper focus primarily on classroom observations along with information gathered from the written student surveys and follow-up interviews.

In analyzing my classroom observations, written surveys, and interview data, I concentrated on both what appeared as consistencies and inconsistencies among students' articulations of selves and classroom practices, the teacher's verbal accounts, and my observations of practices within the classroom. I also examined the role of assessment tools of the classroom in relation to the students', the teacher's, and my perceptions of their emerging mathematical identities.

### **Theoretical Framework**

My analyses are guided by sociocultural perspectives on learning, practice, and identity. I begin with Lave and Wenger's (1991) notion of a community of practice. Communities of practice are defined as:

a set of relations among persons, activity, and world, over time and in relation with other tangential and overlapping communities of practice. A community of practice is an intrinsic condition for the existence of knowledge, not least because it provides the interpretive support necessary for making sense of its heritage. (Lave & Wenger, 1991, p. 98)

If we consider the mathematics classroom as a community of practice, and specifically this discrete mathematics class, then the students and teacher are constantly negotiating and mediating the learning that takes place through their interactions. "Students do not just learn methods and processes in mathematics classrooms, they learn to

be mathematics learners and their learning of content knowledge cannot be separated from their interactional engagement in the classroom, as the two mutually constitute one another at the time of learning” (Boaler, 2000, p. 380, italics in original).

Lave and Wenger (1991) define learning as an aspect of changing participation in evolving communities of practice. As Boaler and Greeno (2000) note, “according to this view, *participation in social practices* [italics added] is what learning mathematics is” (p. 172). Wenger (1998), building on Lave and Wenger’s (1991) theory of communities of practice, writes of identities as developing in *social* practice. “An identity ... is a layering of events of participation and reification by which our experience and its social interpretation inform each other” (p. 151). He uses the concept of trajectories of participation to explain his conception of identity. “As we go through a succession of forms of participation, our identities form trajectories, both within and across communities of practice” (p. 154). Wenger contends that identity is a relational process that is both individual and collective and incorporates the histories and practices of both the self and others, and that it is temporal.

It follows that students are indeed developing identities in the social practices of their mathematics classrooms, and in conjunction with Lave (1996) and Wenger (1998), we need to examine this identity development in order to examine the learning that is taking place in mathematics classrooms. I am interested in the mathematical identities that are constructed and re-constructed in relation to the valorized mathematical practices of the classroom (de Abreu, 2002). I say this keeping in mind that the mathematical content knowledge we take with us is an integral part of our “mathematical identity.”

I make the distinction between mathematical identity and identity as I only observed these students’ formation and development of their identities in the figured world (Boaler & Greeno, 2000; Holland, Lachiotte, Skinner & Cain, 1998) of this specific mathematics classroom. Holland et al. (1998) define a figured world as “a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others” (p. 52). One’s identity in the figured world of classroom mathematics depends on past participation (history) in mathematics classrooms, or communities of practice. It also depends on a number of other “identities”: larger structural identities such as “gender, race, ethnicity, or any other durable structural feature of the society” (Holland et al., 1998, p. 7) or identities based on other less structural figured worlds. In similar communities of practice, such as mathematics classrooms that value similar practices, students may construct more durable mathematical identities. But, depending on past participation or participation in other communities, this may not prove viable for all students.

### Research Findings

I present the results of this research in four sections. First, I examine the valorized practices of this particular community of practice. Second, I show the relationship

between students' perceptions of what constitutes a "good" mathematics student, their definitions of selves as learners of mathematics, and the valorized practices of the classroom. Third, I examine the contradictions inherent in some of the valorized practices, and fourth, I document how some students negotiated their mathematical identities with respect to the valorized practices of the classroom. Throughout these findings, I present the students' emerging mathematical identities as a relation between how they positioned themselves, how they were positioned by others, and their participation in the valorized practices in this community.

### **Valorized Practices**

From my analyses, I concluded that, within this classroom, three classroom practices were valorized; that is, the teacher and the students engaged in these practices successfully and articulated this engagement well. The three interrelated practices were: (1) working collaboratively in groups, (2) students' and teacher's sharing of knowledge, and (3) clear explanations of mathematical processes. Ms. Smith explicitly endorsed the practice of collaborative learning in mathematics in both an interview and while teaching. As noted in the methods section, Ms. Smith chose to group her students into tables of four. Students were expected to work on all assignments in groups, including formal assessments. Her belief in collaborative learning was closely tied with her belief in inquiry. As a teacher, Ms. Smith articulated her job as to help the students construct their own mathematical understandings through doing. It was rare for Ms. Smith to conduct class didactically; and when she did, I never saw her do so for more than fifteen minutes. She encouraged questions from students, but more often than not, would either re-direct such questions back to the collective, or would suggest that a student ask another student his/her particular question. Ms. Smith's consistent inquiry endorsed the second valorized practice of students and teacher sharing their knowledge with others. Students discussed their assignments both in and across groups. Certain students, as will be addressed in subsequent sections of this paper, moved from group to group either as "information gatherers" or as resources for the other groups. The third valorized practice, that of providing clear explanations, was an effect of both the practice of collaborative learning and the teacher's ability to provide cogent explanations of mathematical processes. Students questioned one another further if they did not find another student's explanation valid or clear. Certain students were praised for their exceptional explanations by their peers and by the teacher.

Important to note, though, is that whereas the practices identified above were both agreed upon by the teacher and the students, there were spaces within the classroom that did not fully support such practices. Although students were expected to complete all assignments, including formal assessments, within their groups, Ms. Smith consistently graded the students on the basis of individual work. At the end of each period, students individually handed in their work to Ms. Smith. She then awarded "power stamps" to each person, depending on the amount and quality of the individually writ-

ten work. At the end of the week, students turned in their stamps from the week and received a grade for their class work. Thus, stamps, on the basis of individual written work, were the valued currency of this community. In addition, Ms. Smith posted an updated ranking of the students each week along with all of their grades. Students regularly consulted the rankings to check their grades and to find out what assignments they were missing.

### **The Interrelation of the Students' Perceived Ideal Learner of Mathematics and Perception of Self**

Students appeared to develop a situated perspective of what an ideal learner of mathematics was with respect to the valorized practices of this classroom. Further, regularly attending students re-constructed their own mathematical identities with respect to these notions of the practices of a "good" math student. In this section, I document the interconnection between the perceived ideal learner of mathematics in this classroom and students' perceptions of their mathematical selves.

On a written survey, I asked students to give characteristics of a "good" math student. Students tended to agree that successful learners of mathematics were those students who paid attention in class, who helped others or asked for help when necessary, and were who willing to work at building mathematical understanding. There was relatively little in these responses that conjured up typical images of successful students of mathematics (numbers, counting, speed, etc.). In fact, only two students made any such reference in their definition of a "good" math student. Students, for the most part, defined a "good" math student on the basis of what was rewarded in this particular community of practice. These characteristics clearly reflected the valorized practices earlier discussed, and demonstrated the students' valorization of these practices.

Another frequently cited characteristic of a successful student of mathematics was "coming on time." While in some schools, arriving to class before class begins may be a norm, in this school it was not. First period began at 7:45 am. Yet, there were usually 7 or 8 students present at the official beginning of class. About 10 more arrived by 8:00. After 8:00, both Ms. Smith and the school<sup>3</sup> as a whole began marking students as officially late. Students were given one power stamp if they arrived on time and began working on their "pre-class" problems. Coming "on-time" to class was a desired practice, one which included a valued external reward (one power stamp) and was reinforced at both the classroom and institutional levels. With this information, it makes sense that students perceived a "good" math student in this particular community as a student who arrived on-time for class.

The absence of "typical" mathematical discourse in these definitions of "good" math students is significant in understanding this community. As I mentioned before, only two students made direct reference to typical mathematical descriptors. Both were students who did not attend class regularly<sup>4</sup> and were failing the class. One wrote,

"[A good math student is] a number cruncher or someone who has no problem being able to break out the ruler or the tape measure and go to work" (Mark, Survey, 12/12/01). Important to note is that Mark transferred to this school in November 2001. The second student wrote, "[A good math student is a] fast thinker, good with numbers, me" (Tommy, Survey 12/12/01).

Their perceptions of "good" math students are vastly different from the majority of the class. In the case of both of them, it could be argued that because neither one regularly attended school, they were "less-engaged peripheral participants" (Lave & Wenger, 1991), and due to their limited engagement, did not value the same practices as the other students. Lave and Wenger (1991) write,

Peripherality suggests that there are multiple, varied, more- or less-engaged and -inclusive ways of being located in the fields of participation defined by a community. Peripheral participation is about being located in the social world. *Changing* locations and perspectives are part of actors' learning trajectories, developing identities, and forms of membership. (pp. 35-36, italics in original)

I argue that Mark's and Tommy's location in the social world of this particular community, as members who are not regularly present, contribute to their different perceptions of "good" math students.

I now share students' perceptions of their mathematical selves. I argue that one's developing mathematical identity is in part relative to what is taken to be the valued perception of a "good" or "successful" math student in this community. In an attempt to have students articulate how they perceive themselves as learners of mathematics, I gave them a written survey about their practices in this particular community. After receiving written responses from 30 students, I was able to interview 21. At the time of these interviews, I had visited the class 20 times and was able to ask them how their classroom practices related to their perceptions of self.

An overwhelming majority of students claimed that they were "good" in mathematics. Only 2 of 30 students said that they were not good in math. Of the 21 students I interviewed, 1 said she was not good at math and was not improving, 18 said that they felt they were currently becoming better at mathematics, and 2 claimed that they have always felt "good" at mathematics, and felt the same in this particular classroom. Because student surveys and interviews were both measures of students' perceptions of their participation within this particular community of practice, I recognized the necessity to triangulate this data with my own classroom observations, the teacher's observations, and forms of assessment. Thus, I offer multiple perspectives in the following discussion on students' perceptions of their mathematical selves.

The fact that the majority of students identified themselves as becoming better at mathematics was very encouraging. My own observations agreed; I noted throughout my formal observations that most students appeared to be gaining proficiency in not

only using their mathematical content knowledge, but also in their ability to work effectively with others. I was curious to find out why it was that students in this class consistently articulated a positive movement in their trajectories of participation in this particular community.

Elijah consistently earned a B in this math class. He completed all his assignments, was on time for class everyday, and regularly participated in whole class discussions. On his written survey, he claimed he generally did not think he was good in mathematics, but he did feel he was successful in this particular mathematics community. I interviewed Elijah the following day. I was curious about his response in relation to his relative success. I asked him if he had always felt unsuccessful in mathematics.

Elijah: Not always. It's just like, when I started, probably eighth grade on up I stopped doing math well and I stopped going to math classes. By the time when I come back in, I don't know what's going on. I'm lost, and everybody ahead of me and stuff. So I felt like I wasn't that good in math. I can do this stuff in here. Because the way Ms. Smith teaches.... Cause it's like, we in a group, it's four of us. There's always somebody in the group that knows it, like say there's something on the board, and like three people don't know it, somebody in the group gonna know it, and he's gonna help everybody in the group. That's how it is. ... It seems like nobody in the group's smarter than anybody else. Everybody has trouble with something, and everybody just helps each other when you're doing this stuff.

K: What specifically about Ms. Smith's teaching has made you feel this way?

E: (3.0)<sup>5</sup> She just, (2.0), the way she just teach. She's like, you could have, you could have, I mean she can crack a joke while we're doing our work, it's like fun in there, and when we having fun, you just do your work. It's not like she's talking you to death. She, she like energetic, and we can do our work in there and stuff, and we having fun. We're doing it. ... It don't even feel like work. Don't even feel like work. (Interview, 12/14/01)

Throughout this passage, Elijah attributed his evolving mathematical identity to practices within the community, and his relations with both his group members and Ms. Smith. It would be important to find out why Elijah stopped doing well in math after eighth grade in a subsequent interview, but for now, it seems crucial to note that first, his self-perception changed within this particular community, and second, that he ascribed this change to relationships in the collective. He noted Ms. Smith's ability to "crack a joke" and her energy; he also noted that within his group, there was a sense of shared power and ability. Each person was valued within the group as an equal, and each person was willing to help the other. My observations concur with those of

Elijah. I frequently noted in my field notes the successful practices of Elijah's group with respect to sharing equally the responsibility to complete assigned projects, and their proficiency at sharing their knowledge with one another. With these interactions acting as an integral part of the learning of mathematics in this community, Elijah was able to alter his perception of self, and in particular, his mathematical identity.

Eboni was consistently either the Number 1 or Number 2 student in the class. Ms. Smith said the following about Eboni: "Eboni is at the top of her class. She pretty much understands what's going on. You know she's like Nicole [another top student in the class]. If she don't understand it they're not going to rest themselves. ... She likes being at the top" (Interview, 10/25/01). In a written survey, Eboni wrote, "I like math a lot. [It] happens to be one of my favorite subjects. On the weekly chart this week I am number one and last week I was two. I think of myself as a good math student." In an interview, I asked Eboni if she had always thought of herself as a "good" math student and she answered no. She appeared to equate success in mathematics with grades, and said that in the past, she had received B's and C's, but now was earning A's.

K: Okay. So since you've been in this class, you've been getting an A the whole time. Why do you think you're doing so well?

E: Because, because she [Ms. Smith] is so good. When she give you problems, she don't make you make it through the problems by yourself. She'll help you, and she'll explain it on the board. She do a good job of explaining stuff. I like how she breaks stuff down. (Interview, 12/13/01)

Just like Elijah, Eboni credited her teacher for at least some of her improvement in math. She characterized Ms. Smith as helping students, explaining mathematics well and "breaking concepts down." Many other students cited these same characteristics as part of the reason why they were improving in mathematics. My own observations indicated that Eboni regularly participated in whole group discussions and often helped other students when they were having problems. Several students cited Eboni as being a top mathematics student. When I asked them why, they said that Eboni understood mathematics, but more importantly, was willing to share her knowledge with others, and could explain clearly. Eboni valued collaborative practices, and because she successfully enacted such practices, perceived of herself as a successful and an improving student of mathematics. In addition, Ms. Smith and the other students positioned Eboni as a successful student for those same reasons.

In fact, 20 of the interviewed students cited Ms. Smith's teaching style (quality of explanations, willingness to help) and working in groups as reasons for either their enjoyment of mathematics or their changing perception of their mathematical ability. Students recognized that they were changing as learners of mathematics and tended to cite more socially constructed practices as promoting such change. What these students articulated was that one's perceived identity in mathematics was not fixed. These

students were in their senior year of high school, and almost all expressed changes in their mathematical identity. They were articulating and naming changes in their trajectories of participation (Wenger, 1998). In addition, the articulated changes were made in respect to the valorized practices of collaborative learning, which included the sharing of knowledge and the production of clear explanations. Because the students were able to envision their own participation with respect to some of the valorized practices of the classroom, I argue that these practices were valorized by both teacher and students. Within this particular figured world, students positioned themselves and sometimes others with respect to such practices. However, as noted before, not all the practices of this classroom were coherent, and consequently, students' trajectories of participation were more complex than perhaps shown thus far.

### **Contradictory Practices**

As noted before, not all practices in this classroom supported the practice of collaborative learning. Students were assessed and ranked individually, and thus although students worked collaboratively, their collaborative effort was not necessarily rewarded in regards to grades. This disconnect between the collaborative learning practices and the assessment practices appeared to cause some tension within the classroom. This tension was a result of not only the teacher's assessment practices, but of larger institutional practices. Ultimately, Ms. Smith had to award individual grades to students; she chose to do so on a daily basis. Thus, students had to negotiate this tension and depending on their positioning within this classroom, took different participatory paths. Hence, different mathematical identities emerged as students participated differentially.

First, I offer the case of Syltee, one of the students who transferred to the school from Sierra Leone in September of 2001. In a written survey, Syltee offered that a good math student was someone who shared her knowledge with others, gave clear explanations willingly, and was "not selfish." Syltee expressed to me privately that some students in this class, especially in her group, did not want to share their knowledge with her.

I used to be good [in mathematics], but when I came here, you know, everybody, they don't share their knowledge, so I just stick on what the teacher told me and when I get home I practice. I think the way I could learn more is the when I mix with my fellow classmates. And when they give me their own knowledge, share the knowledge that they have. When I came here, you know I'm new, when I came in especially this school, most of the students in this math class never share their ideas. They are just selfish. (Syltee, Interview, 12/13/01)

Syltee's perception of a good math student was in part determined by what was valorized in this classroom, and presumably other practices in her life history. Because

Ms. Smith emphasized the value of collaborative work in this classroom, most students expected that their peers would share their knowledge. Syltee's dissatisfaction with some of her peers was relative to the valorization of this particular practice in this classroom. Because she found she could not rely on others to work well with her, she often chose to work alone, and in completing assignments, to use only what she was offered by Ms. Smith. This caused difficulties for Syltee. As mentioned before, Ms. Smith rarely gave explicit directions on how to solve a problem. Rather, she expected students to work out solutions to problems with one another. The case of Syltee helps to identify that not all students fully engaged in collaborative practices. Without peer support, Syltee adopted more individualized practices within the classroom. She experienced a contradiction between what she perceived as valued practices of the community and the enacted practices, and was not satisfied with this inconsistency.

Second, I recall the case of Eboni. While she valued Ms. Smith's clear explanations, and was noted for sharing her knowledge willingly, she identified her self as an improved and successful learner of mathematics in part because she was regularly located as Number 1 or 2 on the wall chart. Thus, it appeared that practices of collaborative learning coupled with individual assessment both contributed to her positive identification of mathematical self.

### **Negotiation of the Valorized Practices**

Students negotiated the valorized practices of collaborative learning and individual assessment, as well as their participation in past, mathematical and otherwise, communities. While the majority of students accepted the collaborative practices of this classroom, and adopted their own participation to meet that of the perceived ideal readily, others expressed more difficulty in negotiating their participation. I turn to the case of Nicole to examine how one student negotiated her position in this classroom. Nicole, mentioned briefly in a previous section, was a top student. She felt that she had always done well in mathematics, but that this year was better for her because she felt she understood more of what she was doing. However, Nicole complained that her group-mates did not always contribute as much as she did. She expressed discomfort with her positioning as a top student in the classroom, and more specifically within her group.

When I work in groups, like most of the time, I'm doing all the work and everybody else copies. Cause they don't like understand it themselves. Instead of trying to take the time to understand it themselves, they just copy my answers. So sometimes I'd rather work by myself. (Interview, 12/13/01)

Nicole was recognized by the members in her group as a quick math student. In class, I observed numerous times that students from her group and other groups asked Nicole for help. She usually agreed to help, but once she began to offer help, was sometimes perceived as not wanting to share her knowledge. It appeared that Nicole

only offered clear and slow explanations when she perceived that the student in need of help was also identified as one of the more successful students in the classroom, such as Eboni. With other less successful students, she spoke quickly and sometimes would take their paper and write the answer with little explanation. Syltee, mentioned earlier, complained that some members of her group did not want to share knowledge; Nicole was one of the members of her group. In part, I attribute Nicole's selectivity in sharing her knowledge to the contradictory practices of the classroom. Nicole's position as top student in the class was reinforced weekly as she consistently was ranked as either Number 1 or number 2 (just as with Eboni). In order to maintain such a position, Nicole chose to share her knowledge with other students who potentially were also beneficial to her, and whose quickness in understanding would not detract from Nicole's own work. Thus, as she participated in exchanges with others, she solidified for some her knowledge of mathematics whereas, for others, was perceived as not wanting to share her knowledge. Nicole's negotiation of this contradiction was tricky; she managed to maintain her position as top student but was not identified by others as successful in enacting the practice of collaborative work.

### Discussion and Conclusion

It appears that a majority of the students in this class constructed an "ideal" math student in relation to the valorized practices of this particular community of practice. This implies that our perceptions of ideals change as we change location within our figured worlds. What may have been perceived as traits of a "good" math student in one classroom may not hold true for another classroom. This also suggests that one's (mathematical) identity is temporal (Wenger, 1998). In addition, the experience of the majority of these students suggests that when students and teachers respect and engage in the valorized practices of the classroom, they experience positive movement in their trajectories of participation. For high school seniors who may have completed their formal mathematical training, it is possible that their positive experiences in this classroom will benefit them outside the classroom as well. It would indeed be informative to follow these same students into the next stages of their lives, tracking their mathematical participation in other communities. This study has shown that individuals develop mathematical identities with relation to their participation in valorized practices of the communities in which they reside.

However, this study has also shown that individuals' negotiation of classroom practices is not a simple process. As with the case of Nicole, it was difficult for her to negotiate contradictory practices successfully. Eboni was more successful at this negotiation in that others noted that she exemplified mastery of the collaborative practices of the classroom, and was a top student. Meanwhile, Nicole sacrificed the way she was identified by some students in order to remain individually a top student.

Wenger (1998) writes, "[F]ocusing on identity brings to the fore the issues of non-participation as well as participation, and of exclusion as well as inclusion. Our

identity involves our ability and our inability to shape the meanings that define our communities and our forms of belonging” (p. 145). This paper argues that as students come to share meanings of what are valorized practices in the classroom, they shape their practices in relation to this valorized ideal. As noted in an earlier section, only 25 of 40 students attended this class on a given day. The students who were more peripheral participants did not experience the same development in their mathematical identities, although they certainly did develop. Non-participation, as Wenger notes, is just as important as participation is in temporal identities. It is indeed difficult and challenging to document the trajectories of students who do not regularly attend class, yet their non-participation is also critical to their own mathematical identities as well as the mathematical identities of the more central participants.

Analyzing students’ developing mathematical identities can be quite informative, as the process of identity is a relational one, and requires researchers to document students’ trajectories of participation. As Lave and Wenger (1991) note, changes in one’s participation indicate that one has learned. As a student’s participation changes, her identity is also developing. As Wenger (1998) argues, learning and identity are interrelated. When we take identity to be a unit of analysis, we are able to make the social practices in which one engages the focal point of our studies. Studying social practices in mathematical communities lends insight into the relationship between valorized practices and success as learners of mathematics. Such analysis also allows us to examine closely the relationships actors develop with one another, and how students and teachers position each other and their selves with respect to the practices of the classroom.

### Notes

<sup>1</sup>A small learning community (SLC) is a school within a school. They are implemented in this district to promote more intimate settings in large high schools.

<sup>2</sup>All names used in this paper are pseudonyms. All participants in this study have chosen their own pseudonyms.

<sup>3</sup>The school has an explicit lateness policy for first period. If a student arrives after 8:00 am, s/he is sent to a “Late Room” and is released to go to class at 8:30 am.

<sup>4</sup>For the purpose of this paper, I define “regularly” as a student who is present 2/3 of the time.

<sup>5</sup>(3.0) represents that it took three seconds for Elijah to respond.

## **SOCIAL CONSTRUCTIVISM IN PRACTICE: CASE STUDY OF AN ELEMENTARY SCHOOL'S MATHEMATIC PROGRAM**

Roland G. Pourdavood  
Cleveland State University  
r.pourdavood@csuohio.edu

Lawrence V. Svec  
Shaker Heights City Schools  
svec\_l@shaker-heights.k12.ohio.us

Lynn M. Cowen  
Shaker Heights City Schools  
cowen\_l@shaker-heights.k12.ohio.us

This research report investigates the following questions: 1) Can social constructivist theory be implemented to raise achievement levels of African American students? 2) What impact does social constructivist theory have on the structure and culture of school? This research report tells the story of a K-4 elementary school that struggled to reform mathematics education (1990-2001) by implementing social constructivist theory in classrooms. After eight years (1990-1998) of focusing on restructuring and reculturing mathematics classrooms, fourth grade students' scores on state mathematics tests dramatically improved for a three year period: 1999-2001. The test results attracted local and statewide attention because African American and white students achieved at about the same high level. The school enrolls 525 students: 60% African American, 33% white and 7% other racial/ethnic groups.

### **A Bit of History**

In 1990, the school principals and teachers implemented social constructivist theory in most classrooms. State mandated testing began in 1995. Educators at this school then faced the political pressures of state tests. The publication of the test results disturbed the climate of this learning community. In 1998 only 69% of fourth grade students passed the mathematics test, which was below the average score of other elementary schools in the district. Because of the test results, some parents, teachers, school board members and central office administrators questioned the credibility of the reform. School principals and teachers searched for ways to blend social constructivist practices with preparation for the state mathematics test. In addition to closing the achievement gap between white and African American students on the state test, the reform confronted the challenge of teaching high-level mathematics to all students so that students and educators could meet the goals of a postmodern society. The potential of social constructivist learning theory became evident when parents actively supported this framework for mathematics learning even when test scores were low. Parent support, confidence and enthusiasm increased when the 1999 mathematics scores showed a dramatic improvement (69% to 90%). Mathematics scores continued to improve over the next two years and the achievement gap continued to narrow.

### **Theoretical and Philosophical Assumptions**

The theory and philosophy of this study were influenced by social constructivist epistemology (Cobb & Yackel, 1996). Social constructivist theory posits that learning and knowing is built via active and interactive activities in a classroom. This theory values time for discourse among members of the learning community and time for building or drawing models of mathematical situations. In addition, the theory recognizes prior and present experiences, relevancy of context, and the value of multiple perspectives. Social constructivist theory assumes a teaching-learning environment beyond the rote and routine learning of basic mathematics skills, not in place of learning basic skills. Social constructivist teaching practices emerged as an important feature for students' understanding of mathematics beyond the limited memorization of basic facts and mechanical procedures. In this sense, classroom practices focus on: dialogue, prior knowledge, mathematical modeling, multiple solutions, students' preconceptions, problem-solving/writing and the importance of context for building understanding.

### **Methods and Study Design**

The study was grounded in the constructivist inquiry of Lincoln and Guba (1985, 1994). Participant-observation, long interviews and review of public documents were used to collect information. Interview data included the transcription of audiotapes from interviews with teachers, principals, assistant superintendents, community officials, parents, and students. Field notes were used when the primary researcher observed and participated in the teaching-learning process. Most data were collected over a three-year period (1999-2001). Additional data sources were triangulated and negotiated among the researchers for trustworthiness of data analysis. Based on multiple data sources, several themes emerged and categories were developed.

### **Lessons Learned**

Seeing how you ask probing questions, and how you get students to talk about what they are seeing. That's probably my favorite part. It's really not only teaching me about math, but also teaching me how I can be a better teacher. (First year teacher, involved with extended time programs)

Major mathematics reform at the elementary level probably requires structural and cultural changes. Implementing social constructivist practices in elementary mathematics classrooms may call for changing conventional teaching-learning-assessment practices.

I taught, years ago, in a very traditional classroom. And, I taught exactly like my advising teacher taught. She introduced me to a college professor who was doing math differently. I had been a very apprehensive math student but she was teaching this [math] and showing it through games, manipulatives

and stuff. It was fascinating to me. I lapped up everything I could. I'd tell the kids that I didn't understand this [mathematics] when I was your age. I didn't have a clue what mathematics was. It's kind of neat, look! (Fourth grade teacher at the K-4 school)

Mathematical illiteracy in America is documented. Most parents and teachers did not learn mathematics in a social constructivist classroom where instruction focuses on the development of mathematical concepts. Many teachers and principals may need to relearn mathematics. Some parents and concerned citizens may also need to view mathematics education differently. Most school schedules (day and year) do not provide enough time for the effective implementation of social constructivist practices. Classrooms are often not equipped with resource materials that support active, interactive instruction. Some researchers believe that computers and calculators are also necessary in a social constructivist classroom. Therefore, schools may need more technology to support changes in mathematics education.

### Structural Changes

I think it's a shift in the way that you think about yourself as a teacher. I think the biggest change is getting people to want to devote more time and more energy to improving mathematics education. (Principal, K-4 school)

It's a very focused curriculum. Focused on big ideas and on the skills necessary to take those big ideas and apply them to real world situations. The problems that we give the kids are highly contextual. So if you were asking me what makes this different from what you might see in other classrooms, I would think that in other classrooms mathematics is driven by textbooks. There are no books here. (Assistant Principal, 1995-2001)

Teaching all students to understand and apply key mathematical ideas within a social constructivist framework necessitates extending instructional time. Some students need extended time to learn and understand mathematics. Mathematics classroom instruction at this K-4 elementary school was extended from 45 minutes to 90 minutes for all students.

If you are going to apply it [social constructivism], if you're going to build and draw models, role play it, and have time to correct and discuss misunderstandings, change your mind and rebuild things, and come back and revisit things, and try to put it all together, that takes time. (Principal)

Students who were still underachieving at the third and fourth grade level were invited to participate in an extended school day, week, and year. Morning and afternoon tutoring was provided (75 min. before school for 4 days each week, 45 min. after school for 3 days each week). Tuition-free summer school was offered for 6 weeks, 3.5

hours per day. Saturday School for fourth graders was held from early September until mid-March for 3.5 hours each Saturday. Students who participated in extended time initiatives had about 250-300 more hours of instruction prior to taking the state mathematics test. About 90% of participating students in extended time programs were African-American whose parents drove them to school early each Saturday morning and early to school 4 days a week.

Most instruction during these extended sessions was conducted within a social constructivist framework. Computers and mathematics software programs were used extensively to support classroom instruction. Social constructivism in practice demanded more instructional time because it went beyond basic calculation skills toward an emphasis on understanding how calculation skills are used in real life contexts. The Kumon Mathematics Program which is more representative of behavioristic instructional practices, was used in after school tutoring sessions and offered free of charge to students. The researchers were uncertain that all students could effectively learn basic facts within a social constructivist framework. Also, the researchers were aware that there was little time to teach both basic skills and conceptual understanding in order to improve student achievement on state tests. The Kumon program was done after school and away from regular classroom time so that teachers could focus on learning mathematics within a problem-solving and problem-finding environment.

### **Cultural Changes**

It's the leadership of the building, number one. There is a real commitment to the fact that all students can learn. There is not a student at this building that can't learn. I see an emphasis on the extra time that the students need to learn as a big priority at this school. They are doing whatever it takes here to get it done. A lot of parents almost come to expect it. I also see a focus on curriculum a lot more intense here than at some of the other buildings [district schools] in terms of the most up-to-date practices and what the most up-to-date research says about how we're teaching. Some of those practices are put into play here at this building. (Assistant principal, 2001-2002)

Mathematics is hard and sometimes it can be fun but it is hard. I want to learn mathematics but also I want to have fun while I do mathematics. I have to think a lot while I am problem solving at [name of the school]. We have to explain our reasoning. We have to draw pictures of money when we are solving problems. We do a lot of discussions while we are solving fraction problems. I like fractions and I like graphing. It is fun to put stuff on the chart and color it in to measure. There is not one way to answer a question, there is always another way you can do it. In problem solving you have to use your mind, you have to go way back when you explain, you have to use all your knowledge (Fourth Grade Student).

Using a learning theory that moved away and beyond behaviorism created disequilibrium for mathematics education. Mathematical processes and mathematical ideas started to be viewed as less definite and more probabilistic than most parents and teachers had learned when they were young. Most teachers learned more about mathematics and the application of mathematical skills and concepts. Some teachers began to view mathematics as a creative process. They taught students to create different patterns, to understand probability, and to design different strategies for solving mathematical problems. Many parents learned to appreciate, enjoy, and view mathematics as a creative art. Many parents also respected their child's use of discourse, illustration, and concrete models to build understanding about important mathematical concepts.

Perhaps the most interesting lesson learned from this reform process was the importance of "student voice" in mathematical discourse. Discourse and "student voice" provided opportunities for student self-reflection and opportunities for teachers to understand what students did not know and what to do next. This recursive relationship between "student voice" and classroom discourse was pivotal for reforming instruction and curriculum. Guided by "student voice" and classroom dialogue, teachers realized that textbook instruction and standardized courses of study might be contextually limited. It seemed that the value placed on "student voice" and student discourse provided a more open, respectful and democratic environment for the mathematics classroom. "You don't know what they're thinking unless you ask them. I only get it [instructional decisions] from the voices of students. They greatly impact the instructional path that I take." (Assistant Principal, 1995-2001)

### **Politics and Reform**

The political environment that surrounded mathematics reform at this elementary school was challenging and somewhat explosive. Parents were informed regularly about the purpose and goals of changing mathematics education. Most parents were supportive and encouraging. District administrators were somewhat skeptical and cautious. Politics came center stage when the state began "proficiency" tests in mathematics for fourth grade students. The scores were used to compare and rank elementary schools within the district and throughout the state. The predominately multiple choice and short answer tests were not compatible with this school's constructivist approach to teaching and assessment.

Early in the reform the fourth graders were not scoring well compared to other schools. However, when the principal and assistant principal designed early morning, Saturday, after school, and summer school classes for about one fourth of the fourth grade students, the state mathematics proficiency scores soared to the highest in the district and the state. The educators learned to maintain constructivist teaching prac-

tices within extra teaching and tutoring sessions and the students learned much and scored very high.

Fourth grade students achieved the following mathematics scores over the last three years (1999-2001). In 1999, mathematics proficiency scores were 86.1% passage rate. In 2000, the result was even better—90.9%. In 2001, the students' passage rate was 95.5% with 58% of the class (90 students) scored "advanced proficient." The three-year average was 90.8%.

### **Social Constructivism and African American Students**

I'll tell you what keeps me going, is I can't stand the statistics [the achievement gap between white and African American students]. I look at my classroom list and I see more and more problems and quite frankly, I think, Jeez, these are the same children who are going to be taking care of me when I'm older. And if I can't change this trend, what is going to happen to these kids? (Fourth grade teacher)

State mathematics test results in 2001 revealed a 100% passage rate for white students and a 92% passage rate for African American students. The difference between African American scores and white scores was much smaller than differences between these two racial groups' scores at local, state and national levels. One might conjecture that social constructivist teaching practices within an extended instructional program can effectively raise African American achievement in mathematics.

Most African American students eagerly participated in extended time programs. The study evinces that students enjoyed learning and responded well to social constructivist teaching practices that encouraged dialogue, risk-taking, problem-solving, concrete modeling and the use of technology. Parents were surprised by their students' progress. In 2001, 40% of African American students who were considered "at-risk" in third grade scored "advanced proficient" in mathematics on state tests. The study suggests social constructivist practices can be effective in raising mathematics achievement of African American students.

The problem of African American underachievement in mathematics is filled with complexity, frustration and anger. American public education has been unable to effectively raise African American achievement in mathematics. Failure to educate African American students in mathematics limits their access to jobs in a technological society. This failure has economic and social justice implications. The study may offer some ideas how to raise mathematics achievement among African American students. "The agenda is primarily social...I think that the Emmy, the Oscar, the Grammy will go to the person who can combine the social agenda with the academic agenda." (Principal)

## Uncertain Future

He's been hiring people who are wonderful teachers and wonderful people. But, he's really, I guess he let's them know that a lot is expected of them. So when he is looking for a teacher, he's looking for someone that's going to come to school and not only follow their contract, but also do a lot more. I've noticed the teachers that he's hired in the last couple years, those are the ones who are here on Saturdays. If he's able to hire people that are totally dedicated like that, and continue to hire teacher like this as people retire the program will continue. (Fourth grade teacher)

Maintaining and sustaining reform efforts at this school remain a challenge. Many elements within the restructuring and reculturing process are expensive, time consuming and dependent on dedicated, intelligent teachers and administrators. The changes represent a dramatic shift away from conventional mathematics education at the K-4 level. Maintaining these reforms within a changing and controlling bureaucratic institution may be difficult. For example, some experienced staff members retire. Other experienced staff members leave for family obligations and career advancements. It is not easy to acquire and educate new administrators about mathematics, social constructivist learning theory, and social constructivist instruction. This type of instructional reform requires an ongoing passion toward adult learning, creative instructional design, and more instructional time for some students.

In addition to the uncertainty that comes with personnel changes, this type of reform may be threatened by district decisions to purchase textbooks and instructional guides that package content, predetermined instruction and give teachers a "crutch" that allows them to avoid active and creative instruction. The reforms at the school were achieved without standard textbooks because teachers and administrators trusted the research about textbook-driven mathematics instruction. Some research suggested textbook instruction hinders creative, active-interactive instruction.

Overall, the reforms represent a major commitment to teacher-administrator learning, to teacher as designer of instruction, to teacher as intellect, to teacher as instructional leader and to the education of all children even though it must happen outside the conventional school schedule. This research implies that the reform will not sustain itself without money, time, and the on-going commitment of teachers and administrators.

## Final Remarks

Creating learning opportunities for all children to make sense of important mathematical concepts may require restructuring and reculturing schools. Fitting social constructivist theory into traditional school schedules and school resources may produce frustration and disappointment until new teaching-learning environments and new time schedules are designed. Findings suggest that social constructivist theory

helps teachers and learners move beyond the limited mathematical information gained through practices designed from behaviorist theory. However, reaching all students with mathematical understanding may also require more money, more time, more resources, and a radical philosophical shift for mathematics teachers and educational leaders.

And there are so many unknowns. The structure is not big enough for this reform. It doesn't fit. I've used comparisons like a box. The current instructional box isn't big enough to hold this change. It's not just 'thinking out-of-the-box' either. That might be easier. It's that you don't have a box big enough to fit what you need. The instructional frame isn't big enough to fit the art of it, the beauty of it. You need a bigger frame. I've looked for appropriate metaphors or similes that would fit all of this and explain it to people clearly. It's just not so simple to explain this whole effort. (Principal)

# MATHEMATICS CLASSROOM DISCOURSE AND THE EDUCATIONAL EXPERIENCE OF DIVERSE STUDENTS

Dorothy Y. White  
University of Georgia  
dwhite@coe.uga.edu

This study examined how four third-grade teachers applied their understandings of their professional development experiences to their classroom discourse and whether the discourse enhanced the educational experiences of their diverse student populations. The results indicate that although each teacher changed some aspect of her classroom discourse, some teachers were more equitable in their distribution of questions across student gender, race, and achievement.

## Theoretical Framework

School systems across the US are engaging in educational reform that demands higher educational standards and results. Mathematics education has received a large share of the attention because of the growing need for schools to produce more quantitatively literate citizens. No longer can schools allow large number of students, especially African American and Hispanic students, to leave school underprepared for the technological society in which they will live and work. Yet the disparities in mathematics achievement among students are well documented (Strutchens & Silver, 2000; Tate, 1997). For example, data from the 1996 NAEP (Strutchens & Silver, 2000) found that the average proficiency of African American and Hispanic students at all grade levels was considerably lower than that of White students. These differences were especially substantial on tasks that called for extended responses and complex problem solving. Although African American and Hispanic students have made achievement gains in recent years, these gains have been only on low-level, basic mathematics skills. As Secada (1992) notes, basic skill proficiency is not enough for "true knowledge and mastery of mathematics" (p. 630). Instead, all students "need to learn a new set of mathematics basics that enable them to compute fluently and to solve problems creatively and resourcefully" (National Council of Teachers of Mathematics [NCTM], 2000a, p. 1)

The poor academic performance of African American and Hispanic students in mathematics is attributable, in part, to their educational experiences in mathematics classrooms (Campbell & Langrall, 1993; Oakes, 1990; Secada, 1992). According to NCTM (2000b), "students' understanding of mathematics, their ability to use it to solve problems, and their confidence in, and disposition toward, mathematics are all shaped by the teaching they encounter in school" (p. 17). Researchers who have examined the educational experiences of African American and Hispanic students report that these students are disproportionately placed in low-tracked mathematics classes that are largely taught by direct instruction, rely heavily on worksheets, and cover less

of the curriculum (Oakes, 1990; Secada, 1992). In these classrooms, teachers spend more time directing students on repetitive tasks, remedial work, and conformity to rules than they spend on developing students' mathematical competence and autonomous thinking. However, research supports the view that students do not learn mathematics effectively when passively listening to teacher directions.

Developing children's mathematical thinking through classroom discourse has attracted considerable attention in recent years (Davis, 1997; Elliott & Kenney, 1996; Kazemi, 1998; Lo & Wheatley, 1994; Martino & Maher, 1999; National Council of Teachers of Mathematics, 1991; Pirie, 1996). Research on classroom discourse often cites the NCTM (1991) recommendations that mathematics teachers initiate and orchestrate discourse by posing questions that elicit, engage, and challenge students' thinking; by listening carefully to students' ideas; and by asking students to clarify and justify their ideas orally and in writing. Classroom discourse centered on mathematical reasoning and sense making allow teachers to stimulate students' thinking and to reflect on students' understanding. Teachers can promote students' growth of mathematical knowledge by asking more open-ended questions aimed at problem solving and conceptual understanding (Martino & Maher, 1999). More importantly, productive classroom discourse requires that teachers engage *all* students in discourse by monitoring their participation in discussions and deciding when and how to encourage each student to participate. By actively listening to students' ideas and suggestions, teachers demonstrate the value they place on the students' contributions (Davis, 1997; Pirie, 1996).

Engaging all students in classroom discourse has direct implications for equity issues in mathematics education (White, 2000). For example, the nature of teachers' questions, whom she/he selects to respond to these questions and whose answers are accepted and valued can impact student achievement and participation. An equitable learning environment is one where every student is afforded an opportunity to learn mathematics, participate in mathematics lessons and discussions, and have their ideas valued and respected. Thus, if communication is essential to the learning of mathematics, then researchers need to examine the nature and type of communication occurring in classrooms of diverse student populations. As Hart and Alexsaht-Snyder (1996) specifically suggest, we need more research of teacher development programs that focus explicitly on teachers of diverse students and the sociocultural contexts of mathematics learning in their school settings.

### Method

This research examined how teachers applied their understandings of their professional development experiences to their classroom discourse and whether the discourse enhanced the educational experiences of their diverse student populations. Central questions for this research were:

1. What changes occurred in the nature of teachers' classroom discourse before and during participation in Project IMPACT?
2. What changes occurred in the questioning patterns between teachers and their students across students' gender and race before and during participation in Project IMPACT?

### **Participants**

Four third-grade teachers and their students in a large, urban school district located just outside of Washington, DC participated in this study. The teachers and students were part of a longitudinal research study entitled Project IMPACT (Increasing the Mathematical Power of All Children and Teachers) to design, implement, and evaluate a model for mathematics instruction in schools serving children of diverse ethnic and socioeconomic backgrounds. All of the teachers were White females. Three teachers, Ms. Atkins, Ms. Davis, and Ms. Tyler, were first-year teachers. Ms. Smith was the most experienced teacher in the study. She had taught a total of eighteen years at the primary level, six of those years in third grade. A total of 172 third-grade students were included in this study: 79 students before Project IMPACT and 93 students during Project IMPACT. The students represented various ethnic groups and were classified into the following categories: Asian, Black, Hispanic, and White. This racial categorization was based on the school system's policy for classifying students. Any student who was not considered Asian, Black, or Hispanic, as defined above, was classified as White. In this study, only two non-white students were placed into this category. In both cases, the students were from East-Indian descent. Tables 1 and 2 show the racial and gender breakdown of the students in each of the four classrooms, before and during Project IMPACT.

### **Project IMPACT**

As participants in Project IMPACT, teachers attended a 22-day summer enhancement inservice where they reviewed mathematics reform documents, examined research on classroom discourse and questioning techniques, mathematics equity, and teaching for understanding to culturally diverse populations. Ten mornings in the summer, teachers taught small groups of third grade students to practice the ideas expressed in the inservice. Teachers were also supported during the school year following the summer inservice with an on-site mathematics specialist. For more information on Project IMPACT, see Campbell and White (1997).

### **Data Sources and Analysis**

Classroom observations, supplemented by my field notes, provided the first source of data for this study. Prior to their participation in Project IMPACT, I observed each teacher teaching mathematics on four separate occasions. This provided me with background information on the teachers' initial classroom discourse and their distri-

bution of questioning patterns. To examine the changes in these patterns, I observed the teachers teaching mathematics on eight separate occasions from January to June of the academic year following the Project IMPACT summer inservice. After the last classroom observations, I individually interviewed each teacher to gather data about her perceptions of the classroom discourse, questioning patterns during mathematics instruction, and whether her views were consistent with her actual classroom practices. These semi-structured interviews provided the second source of data for the study. The journals that teachers wrote during the summer inservice also provided a third source of data to document changes in the teachers' beliefs about teaching mathematics for understanding, mathematics education reform, and educational equity issues.

A separate set of analyses was conducted for each teacher using methods of analytic induction (Bogdan & Biklen, 1992). I chose a qualitative perspective because it afforded me the opportunity to describe the teachers' classroom discourse and questioning patterns in a naturalistic setting while attending to both the content and context of the discourse (Carlsen, 1991). Transcripts of classroom observations and field notes were first analyzed by examining the teachers' question and response patterns and categorizing the patterns into themes based on the nature and focus of the discourse and the cognitive difficulty of the questions. Questions were considered either low-level or high-level. Once the themes were identified and assigned to units of data, these themes were analyzed to identify the students that were involved in the interactions based on categories across students' gender and race (Irvine, 1985; Simpson & Erickson, 1983). This analysis helped answer the second research question, regarding the discourse patterns between the teachers and their students across students' gender and race.

## **Results**

### **Changes in Classroom Questioning Patterns**

The teachers in this study entered the Project from various points of instruction. Three teachers were traditional in their approaches to teaching mathematics before their involvement in Project IMPACT. They began their lessons with a review of a topic, followed by assigning a worksheet of problems for the students to solve. These teachers, Ms. Atkins, Ms. Davis, and Ms. Smith, directed students on the mathematical skills, concepts, and procedures they should use to solve mathematical problems. Ms. Davis wanted her students to know that there was more than one way to solve mathematics problems and often demonstrated various solution strategies for the students to use as they solved problems. Ms. Tyler taught mathematics from a hands-on approach where students worked on problems in various contexts. Although she included several open-ended tasks, she expected students to solve problems in a prescribed manner and emphasized the procedures students were to follow. In all the teachers' classrooms, students worked with manipulative materials; however, manipulatives were either used to explore ideas as in Ms. Smith's class, or to solve problems in a specific manner.

The most common question and response pattern for all four teachers, prior to their involvement in Project IMPACT, was defined as Pattern 1. In this pattern, the teacher asks a question, the student responds with the correct answer, upon which the teacher acknowledges the response and moves the lesson along. For these Pattern 1 interactions, the teacher accepts the student's correct answers without question. She does not probe the student to explain how he/she arrived at the correct answer. Instead, she assumes the answer implies correct thinking. The number of teachers' questions coded as Pattern 1 before Project IMPACT were: Ms. Atkins, 78%; Ms. Davis, 58%; Ms. Smith, 58%, and Ms. Tyler, 62%. Thus, a substantial number of all the teachers' questions prior to their involvement in Project IMPACT focused on the correct answer.

The students observed before Project IMPACT mainly asked questions. The majority of their questions were posed to clarify how they should solve problems and to verify whether they were solving problems correctly. Most teachers answered students' questions directly. They assumed the role of mathematics authority as they gave specific instructions on how problems should be solved.

During Project IMPACT, teachers changed the way they approached mathematics instruction. Students were encouraged to work collectively to solve problems and manipulative materials were regularly available and used by the students to solve problems. Mathematics problems were generally in the form of word problems created by the teacher, by the students, or adapted from a textbook. Worksheets of drill and practice exercises were not evident. Rather, problem solving provided the context for classroom lessons.

There was a major shift in focus of the teachers' questions during their participation in Project IMPACT. Most teachers shifted from a focus on the correct answer to the various ways mathematics problems can be solved. They included several new questioning patterns as they taught mathematics and expected students to explain how they arrived at their answers. For example, most teachers posed more Pattern 2 questions in their mathematics lessons. Pattern 2 questions were open-ended and allowed for multiple answers and solution paths. For these questions, teachers selected several students to answer the same question in different ways and often followed up by asking students to explain their answers. In particular, 93% of Ms. Atkins' responses to her Pattern 2 questions were to ask the students to explain their thinking. Ms. Davis, Ms. Smith, and Ms. Tyler also asked students to explain their answers for 47%, 23%, and 68% of their responses, respectively.

Teachers also wanted the class to judge the correctness of the answers offered by their classmates. This pattern was referred to as Pattern 4. In this pattern, teachers asked the class whether and why they agreed or disagreed with a particular answer and/or solution strategy. Ms. Tyler was the only teacher that asked a Pattern 4 question before her involvement in Project IMPACT. However, during the project, all four teachers included Pattern 4 questions in their mathematics lessons. Furthermore, teachers asked Pattern 4 questions for both correct and incorrect responses.

During the project, student talk was not limited to asking questions. While students continued to ask questions for clarification purposes, they were also observed sharing their opinions about the answers and explanations offered by others. Most teachers encouraged student expression with the exception of Ms. Smith. In her class, students were often observed off-task and engaged in non-mathematical discussions. Teachers' responses to student-generated questions also changed during Project IMPACT. Teachers often asked students questions to help them figure out the answers on their own. They wanted the students to be in control of their learning and asked questions to lead them to the correct answer. This was particularly noticed in Ms. Tyler's classroom.

### **Cognitive Level of Questioning Patterns**

The majority of the questions posed by the teachers, prior to their involvement in Project IMPACT, were coded cognitively as low-level. Low-level questions were those requiring students to recall mathematical facts and procedures. In contrast, high-level questions required students to analyze and interpret mathematical concepts based on their prior knowledge and experiences. Teachers asked high-level questions because they wanted students to reflect on and make connections between previously learned mathematical ideas and newly presented problems. During the project, there was a substantial increase in the number of high-level questions posed by all four teachers.

Two teachers, Ms. Atkins and Ms. Smith, posed high-level questions as they taught mathematics before Project IMPACT. Two percent of Ms. Atkins' questions were coded as high-level as were six percent of Ms. Smith's questions. For these teachers, the number of high-level questions posed during the project increased to 26% and 40%, respectively. All of Ms. Davis' and Ms. Tyler's questions were coded as low-level as they taught mathematics the year before their involvement in Project IMPACT. During the project however, the percentage of high-level questions posed by Ms. Davis and Ms. Tyler were 23% and 32%, respectively. Therefore, all four teachers increased the number of high-level questions they posed during their participation in Project IMPACT.

### **Changes in Distribution of Questions**

Before Project IMPACT the majority of Ms. Atkins' questions were posed to Black- and Asian-male students. Black-females were posed a considerable amount of questions, but less than their male counterparts. Furthermore, Hispanic- and Asian-female students were rarely asked to respond to any questions. In contrast, Hispanic- and Black-females were asked a large share of Ms. Atkins' low-level questions, while Asian- and White-females were asked the majority of Ms. Atkins' high-level questions. Another interesting aspect of Ms. Atkins' distribution of questions is that in both years she would select only boys in some lessons, while in other lessons she selected only girls. In both years, Ms. Atkins selected students that could answer her questions correctly.

**Table 1.** Racial Distribution of Students Across Classrooms: Before Project IMPACT

|            | Sex    | Asian | Black | Hispanic | White | Total |
|------------|--------|-------|-------|----------|-------|-------|
| Ms. Atkins | Male   | 2     | 4     | 2        | 0     | 8     |
|            | Female | 3     | 7     | 1        | 0     | 11    |
| Ms. Davis  | Male   | 2     | 1     | 1        | 3     | 7     |
|            | Female | 3     | 2     | 4        | 0     | 9     |
| Ms. Smith  | Male   | 3     | 3     | 5        | 1     | 12    |
|            | Female | 1     | 4     | 5        | 0     | 10    |
| Ms. Tyler  | Male   | 0     | 5     | 3        | 3     | 11    |
|            | Female | 0     | 7     | 1        | 3     | 11    |

**Table 2.** Racial Distribution of Students Across Classrooms: During Project IMPACT

|            | Sex    | Asian | Black | Hispanic | White | Total |
|------------|--------|-------|-------|----------|-------|-------|
| Ms. Atkins | Male   | 0     | 2     | 5        | 1     | 8     |
|            | Female | 4     | 2     | 3        | 3     | 12    |
| Ms. Davis  | Male   | 3     | 4     | 5        | 0     | 12    |
|            | Female | 1     | 4     | 3        | 2     | 10    |
| Ms. Smith  | Male   | 4     | 4     | 6        | 1     | 15    |
|            | Female | 3     | 1     | 4        | 1     | 9     |
| Ms. Tyler  | Male   | 0     | 5     | 0        | 9     | 14    |
|            | Female | 0     | 8     | 0        | 5     | 13    |

Prior to her involvement in Project IMPACT, Ms. Smith selected a White-male student more often than any other student to answer her questions and “rescue” others that gave incorrect answers. This student was selected regardless of whether he volunteered. Ms. Smith’s distribution of questions did not dramatically change as a result of her participation in Project IMPACT. There were several students who were rarely asked to respond during both school years. During Project IMPACT however, there were five students selected to answer the majority of Ms. Smith’s questions across patterns and cognitive levels. These students included a White male, Black male, Hispanic male, Black female and White female. Moreover, they were often selected to help when other students answered incorrectly. Students in other race/sex categories, especially Asian males, were rarely selected to respond to Ms. Smith questions. In Ms.

Smith's classroom, there were students that either always participated in classroom discussions or rarely participated. Instead, these students were often asked to listen and watch, and when they were asked questions, it was usually to clarify that they were on task.

Ms. Davis selected females to respond to her questions more than the males in her class prior to her involvement in Project IMPACT. With the exception of Pattern 2, where she selected an even share of males to females, Ms. Davis tended to ask more questions of girls than boys. More specifically, Black-females were selected more often across questioning patterns, while Hispanic students and White-males were rarely asked to respond. During Project IMPACT, Ms. Davis selected students of all genders and races to respond to both her low- and high-level questions. White-females were asked the majority of her questions across patterns however, all students were selected in one pattern or another a moderate number of times.

Ms. Tyler selected Black- and White-females to respond to most of her questions prior to her involvement in Project IMPACT. Prior to her involvement in Project IMPACT, Ms. Tyler selected a fair number of students from both genders to respond to her questions. Black- and White-female students were selected more often across questioning patterns, while the one Hispanic-female was rarely asked questions. Males of all races were posed a moderate number of questions across patterns, with the exception of questions that required the students to explain their answers. In this case, one White male was selected the most. During Project IMPACT, Ms. Tyler selected students of all gender and racial backgrounds to respond to both low- and high-level questions. For low-level questions she distributed her questions fairly across gender and race, with the exception of Patterns 1A and 2. In these patterns, she selected more Black males and White females, respectively. For high-level questions, there were differences in Ms. Tyler's distributions across race. While students from all race/sex categories were selected to respond to high-level questions, White students of both genders were selected the most. Moreover, the high-level questions that were posed to Black students were usually answered by Black males.

### **Influence of Project IMPACT**

All four teachers believed their questioning patterns changed as a result of their participation in Project IMPACT. During the summer inservice, teachers often expressed feelings of frustration in their journal entries. They were frustrated with their questioning patterns resulting in feelings of inadequacy. However, by the end of the summer inservice teachers believed they had made progress.

Most teachers, with the exception of Ms. Smith, began to realize how their views and beliefs about teaching are directly connected to students' learning. Teachers often made reference to classroom exchanges and how their questioning may or may not have been a factor. Ms. Smith rarely wrote about the students she taught during the summer. Her main focus was on her questioning with little attention to curriculum matters.

The end-of-year interviews revealed teachers were cognizant of the changes in their instructional practices. The teachers were very candid in their interview responses and cited several instances where change was identified. For example, most teachers recognized that they rarely asked students to explain their answers to mathematics problems before entering the project. In reflection, they believed they changed in both the focus and type of questions they posed.

### Discussion

The purpose of this investigation was to examine teacher change as exhibited by four third-grade teachers who were participants in Project IMPACT. The project provided teachers with research on current mathematics reform documents and its implications for mathematics instruction, as well as issues relating to equity. Thus, the study examined how teachers used this information to provide meaningful mathematical experiences for all their students.

The teachers in this study entered the Project from various points of instruction. All four teachers in this study were influenced by their involvement in Project IMPACT and changed their teaching practices. The degree of that change varied but was evident in all four classrooms. Overall, teachers encouraged students to find alternative ways to approach problems and to explain their answers. They used questioning rather than telling to focus students' attention on mathematical concepts. These questions focused more on students' solution strategies and less on correct answers. They also included more cognitively challenging questions into their instruction. More importantly, teachers used questioning to create a classroom environment where thinking and sense making were the norm.

Most teachers encouraged students to exchange points of view. In Ms. Smith's and Ms. Atkins' classes, these exchanges were often initiated by the students. That is, students exchanged their opinions regarding other students' answers or solution strategies without solicitation from the teachers. In contrast, Ms. Tyler was often observed encouraging students to speak to one another as the class listened, especially when they agreed or disagreed. She stepped out of the picture in the sense that she asked another student to share what they thought about their peer's comment. Ms. Davis wanted the class to come to a consensus when they answered questions. She encouraged students to share why they agreed or disagreed with an answer, but she did not select specific students to respond when their answers were debated. Ms. Davis made a special effort to insure that Limited English Proficient students were matched with another student that could translate problems and explanations. However, she still expected all students to do their own work. Ms. Tyler and Ms. Davis seem to be negotiating social norms of discourse in ways described by Lo & Wheatley (1994).

The study also examined issues of equity in relation to the types and distributions of teachers' questions. All students were exposed to the same mathematics curriculum. That is, no form of ability grouping was evident in any of the teachers' classrooms.

However, there were several behavioral problems during Ms. Smith's mathematics lessons. As a result, students were often expelled from the class and moved to another teacher's classroom. These students' exposures to mathematics lessons were limited.

The findings from the study as discussed above suggest the educational experiences of students in some teachers' classrooms varied. Ms. Davis and Ms. Tyler were the most equitable in their distributions of questions and interactions with students. They posed questions to all students across questioning patterns and cognitive levels. They also acknowledged that some students needed more high-level questions than others based on their academic ability. Therefore, students that were higher in academic ability were not selected as much for low-level questions. As Ms. Tyler explained in her interview, lower-achieving students tend to shy away from answering questions if the higher students propose answers they may not have thought of or understood. These teachers wanted to insure that all students shared in classroom discussions, and therefore based their decisions accordingly.

Ms. Atkins selected students based on academic ability. In her classroom, students with the greatest mathematical content knowledge (i.e., those who scored highest on the Project IMPACT mid-year assessment) were selected more often to answer high-level questions. Lower achieving students were selected for more low-level questions and were rarely asked high-level questions. For Ms. Atkins, neither race nor gender seemed to be the deciding factor in her selections. Instead, she posed questions to students she believed could handle the information and respond accordingly. Ms. Atkins' journal entries provide some insight into her selections. In several of her entries, she expressed her concern about teaching mathematics. For example, she wrote: "Many times I find teaching math difficult because there are concepts I don't understand. How do I teach what I don't understand?" Ms. Atkins' selections may therefore be explained by her lack of understanding of mathematical concepts. What is more important, however, is that she wanted to insure that higher-order thinking was included in her lessons. Thus, she selected students that she was confident would give her the correct answer.

Ms. Smith posed the majority of her questions to students with greater mathematical understanding, both before and during Project IMPACT. Before Project IMPACT, one White-male student was disproportionately selected to answer her questions; during Project IMPACT there were five students she selected. The educational experiences with regard to Ms. Smith's questions were clearly different and inequitable for the students in her classes. For Asian-male students in particular, their exclusion from class questions may explain their limited gain on Project IMPACT assessments. Ms. Smith's distribution of questions may also explain the overwhelming numbers of behavior problems in the room.

It is not clear whether Ms. Smith's mathematical knowledge was a factor in her selection of students. She rarely made reference to her mathematical ability in either

her journal writings or interview responses. One explanation for her selections may be her beliefs about which students can and cannot do mathematics. Ms. Smith was the most experienced of all the teachers in this study. On the basis of her teaching experience, she may feel that some students, especially low-level or non-English speaking students, cannot do mathematics. This may explain why she rarely interacted with these students. However, alternative explanations may hold.

For both Ms. Atkins and Ms. Smith, their selections resulted in the differential treatment of students. Unlike Ms. Davis and Ms. Tyler, these teachers did not insure that all students received both low- and high-level questions. Rather, students that were deemed academically ready were posed questions across cognitive levels, while low-level students were mostly asked low-level questions. Thus, the educational experiences of the students in their classrooms varied.

Shaw and Jakubowski (1991) write "the effectiveness of mathematics education reform is only as good as the commitment and willingness of teachers to change" (p. 20). For the teachers in this study there seemed to be a genuine commitment for change. Their commitments developed over time and were a result of several factors incorporated in Project IMPACT. The students also played a role in the teachers' commitment to change. The students in all four classrooms often voiced their opinions about mathematical ideas and solutions. Most students participated in the Project in the previous year and were accustomed to sharing their thoughts. However, the teachers' willingness to accept the students' comments can not be ignored. Recall that most of the teachers were very traditional in their approach to teaching mathematics before Project IMPACT. They told students how to solve problems and rarely asked them to explain their answers. By changing the focus of their questions and acknowledging students' various thinking skills, these teachers fostered mathematical classrooms conducive for learning.

### Conclusion

As we begin the 21st century, the challenge to mathematics education researchers is to address the causes for the disparities in mathematics education and to describe possible solution paths within the context of educational reform (Secada, 1992). This study provided a glimpse of the educational opportunities, experiences, and outcomes of students from various ethnic and gender backgrounds in classrooms of teachers attempting classroom reform. The study also described how classroom discourse can provide a context for examining equity issues in mathematics education. The results from this investigation suggest that teachers can provide meaningful and equitable mathematics instruction when given the knowledge of research, instructional support, and when they have a genuine commitment for change. Future research is warranted to examine how teachers' classroom practices evolve over time and the interplay among students' gender, race, and achievement.

## BUILDING A NEW INTERVENTION MODEL

Yolanda De La Cruz  
Arizona State University West  
ydelacruz@asu.edu

Latino families are growing in numbers as Latino families, currently the largest minority group in the Southwest, have been visibly transforming culture and society. These growing families are seeking ways to improve their status in the United States and look to the educational process as a way of achieving this goal. By including them in partnerships with schools, we can help them reach these goals. This paper outlines a research model for greater family involvement and family participation among Latino families in the area of mathematics. Children's Math Worlds Family Connection component (CMWFC) is part of a reform mathematics curriculum, Children's Math Worlds, was developed for first through third grades, at Northwestern University. The CMWFC component is in the final stages and is being field tested in Illinois, California and in Arizona. These findings indicate that the project holds promise of improving mathematics teaching and learning at the elementary level among Latino students.

Involving parents in their children's learning has been recognized as necessary and important by scholars who contributed to several reports on the nation's schools. The recommendations reflect the consistent findings in social research that children have an added advantage in school when their parents encourage and support schooling. This intervention model represents changes taken by classroom teachers, along with the families to improve the mathematics knowledge of the children. Data collected in a period of four years in the form of students' mathematics test scores, family and teacher surveys and journal entries, along with interviews resulted in the New Intervention Model.

### Context-Embedded Mathematics Instruction

The lack of English proficiency is the major reason for language minority students' school failure. A considerable amount of research from both Europe and North America suggests that minority students frequently develop fluent surface or conversational skills in the school language but their academic skills continue to lag behind grade norms. This surface fluency may mask significant gaps in the development of academic aspects of English. Academic growth will be fostered by context-embedded instruction that validates students' background experiences by encouraging them to express, share, and amplify these experiences.

Children come to school with different degrees of exposure to decontextualized language. When students have had little exposure to such uses of language prior to school, and instruction in school assumes that these uses have been developed already, the resulting "mismatch" can cause considerable confusion for children, as well as difficulty to help children directly learn to use academic style language. Children's Math

Worlds Curriculum exposes children to contextualized language by using their stories and their experiences as the bases from which mathematical concepts are taught. Mathematical growth is developed by starting where the student is academically and embedding concepts that will extend their language usage through their active participation.

### **Meeting Particular Needs of Latino Parents**

School reform programs were developed without sufficient attention toward how to attain the academic goals required for success among Latino and other linguistic and ethnic minority students. In the CMWFC component, parents were asked what they needed in order to help their children in mathematics. Surveys in both Spanish and English were sent home with children and follow-up calls were made to parents who had not responded to the survey. Parents wanted to learn to help their children at home but did not feel they had enough mathematics knowledge to help their first, second, and third grade children. The Building a New Intervention Model outlines adaptations made by teachers to expand the support base of their students. These adaptations allowed all student to have access to higher learning in mathematics and to be come successful in this learning.

### **School Miscalculations and Teacher Knowledge**

The educative process of all homes are important ingredients for society in the United States. Because of the diversity in U.S. families, we do not find one single home curriculum, but many variations. Too often, educators underestimate the power of the curriculum in the home. When this happens, teachers miscalculate and misjudge the learning that children have acquired outside of school.

Research indicates that no matter what the ethnic or socioeconomic makeup of the family, common parental styles and activities support children's growth toward a productive lifestyle. Unfortunately, in some families situations, parental styles and habits mitigate against children's natural pursuit of knowledge and positive development. All families have an organization structure that defines family members and their roles. Even in homeless families, parents have some kind of organizational structure to provide physical and emotional support (Takaki, 1996). Whatever children's environment, they learn who they are, how to use the space, and what kind of a world they live in. And no matter what family structure exists, home learning will be a consequence of family interaction, use of time and space, routines of the day, sharing of interests and skills, family rituals and traditions, and family outreach to others.

Parents are children's first and probably most influential teachers. Common features of parenting imply a curriculum; some families have specific goals for their children's development, while others' intentions are vague and ill defined. This New Intervention Model hopefully will give new direction to the intervention practices that fail to take the family needs into consideration before they are implemented in schools.

The current knowledge base of mathematics teaching arises from previous studies of practitioners who lack constructivist orientations and rely heavily on traditional images and methods of teaching and learning. Therefore, a need for pedagogical models that support constructivist learning goals for children exists. Documenting the instructional practices of teachers who truly allow students to construct their own mathematical meanings seems to be one productive way to generate fruitful descriptions of successful reform mathematics teaching.

A major aspect of such reform classrooms is establishing a new classroom discourse style that focuses on and facilitates children's description and discussion for solution methods and mathematical thinking rather than concentrating on eliciting brief answers to simple teacher questions. The research literature at present has few detailed models of this more complex discourse.

**MATHEMATICS IN CANADIAN CLASSROOMS AND  
SOCIOECONOMIC MATHEMATICS  
ACHIEVEMENT GAP**

George Frempong  
York University  
gfrempong@edu.yorku.ca

This paper explores three main issues: the extent to which students background characteristics affect their mathematics achievement, the extent to which differences in classrooms affect students' mathematics achievement, and the characteristics of mathematics classrooms where students irrespective of their backgrounds succeed in learning mathematics. These issues are consistent of a vision of mathematics education where all students irrespective of their background characteristics are expected to succeed in learning mathematics. The issues are explored employing the Third International Mathematics and Science Study data for grades 7 and 8 students in Canada. Analysis of the data using multilevel models demonstrates a relatively low mathematics achievement of students from low SES families, especially in Proportionality, Measurement, and Fractions indicating that, a student's success or failure in mathematics learning is domain-specific and is also related to the backgrounds of students. However, the socioeconomic mathematics achievement gap vary significantly among classrooms, and there is some evidence that the gap decreases with increasing classroom mathematics achievement levels. This suggests that mathematics achievement is equitably distributed in classrooms with high achievement levels. Thus, there are successful classrooms in Canada, but the most successful classrooms tend to be those where students from disadvantaged socioeconomic backgrounds excel in mathematics. Another important finding from the analysis is that a more equitable distribution of achievement within mathematics classrooms where teachers avoid practices which involve small grouping, where mathematics teachers are specialized, and in schools where pupil-teacher-ratio is low. This finding calls for a deeper examination of how the effectiveness of instructional practices may vary depending of the background characteristics of students.

## **SOME REFLECTIONS ON THE DISCIPLINARY CULTURE OF MATHEMATICS AND ITS IMPLICATIONS FOR INSTRUCTION**

Abbe Herzig  
Rutgers University  
ahherzig@rci.rutgers.edu

The basic beliefs about a discipline, both by its practitioners and its students, form an important part of the context in which education takes place. In this paper, I describe some basic contradictions among common beliefs about mathematics, how mathematicians do their work, and mathematics instruction, and I reflect on the ways these contradictions affect mathematics instruction.

A disciplinary culture, as it is lived at the core of the activity of the discipline, affects the education of the graduate students at that core. Those graduate students go on to become the faculty at many colleges and universities throughout the country (Becher, 1989). Those faculty are then responsible for educating the vast number of students who will become teachers, who then educate pre-college students. Through this “domino” effect, aspects of the disciplinary culture have a profound effect on education at all levels. By looking at the work and attitudes of mathematicians and the experiences of the doctoral students they educate, we can begin to unravel some of the effects of the disciplinary culture of mathematics on earlier levels of mathematics education. This paper is the beginning of the author’s attempt to characterize some important aspects of the disciplinary culture of mathematics and their implications on mathematics instruction. As such, I present a series of loosely-coupled reflections on this issue.

The disciplinary culture of mathematics is comprised, in part, of a set of fundamental beliefs and practices that guide mathematical activity. On the surface, these beliefs and practices exist as a series of tensions between some sometimes contradictory ideas. For example, while mathematicians have strong aesthetic and emotional descriptions and reactions to their work (Herzig, 2002), mathematics is often believed to be “objective” and impersonal. These apparent contradictions actually characterize an important feature of the disciplinary culture of mathematics: mathematics itself lies in an  $n$ -dimensional space, spanned by a basis whose elements define continua between the personal and impersonal, between collaborative and individual work, between solvable and insolvable problems, between the sciences and the humanities. The remainder of this essay explores four of these basis elements, these continua of activity.

First, mathematicians do a lot of their work collaboratively and cite many advantages to collaborative work (Burton, 1999; Herzig, 2002), contradicting the common myth of the “Mathematical Marlboro Man” (Henrion, 1997). However, when Herzig

(2002) asked mathematicians about the nature of these collaborations, they described partnerships in which most of the work was done independently and individually by the collaborators, and put together periodically; some had even written papers with people they had never met. Indeed, mathematicians have been characterized as being very independent (Fennema & Peterson, 1985).

The work of mathematics students at many levels is expected to be individual, and is often competitive. In contrast, recent reform efforts in K-12 mathematics education have emphasized the importance of students working collaboratively to solve problems. What are the ideal roles of individual and collaborative work in mathematics education? Are mathematicians independent because that is a style that is best suited to the nature of mathematics, or, since the social structure is one that requires independence (Herzig, 2002), is it only the independent learners who succeed in mathematics?

Second, the first few years of graduate study in most U.S. mathematics departments consists of students taking courses in preparation for the qualifying exams, which are important filters along the path to the Ph.D. Students who cannot solve the problems posed on a qualifying exam are judged not to be capable of conducting mathematics research. However, as one mathematician explained,

Doing mathematics isn't exactly like answering qualifying questions. . . .  
When I do math I try to keep in my head a lot of questions, most of which I can't solve and then my success is measured by the ones I've solved. It's measured by the papers I've written, and not the ones I've failed to write.

Much of traditional mathematics instruction is built around deriving specific solutions to particular problems, rather than on exploring a host of problems to see where they lead. How and what would students learn about mathematics, if mathematics instruction was built around students' explorations of a host of mathematical problems, even if they are never "solved"? Recent reform efforts at the K-12 level have attempted to move students closer to this exploration.

Third, mathematicians have strong emotional and aesthetic reactions to their work; for example, when they describe the euphoria that comes from solving a problem (Burton, 1999), or when they describe their appreciation for the beauty of mathematics (Herzig, 2002) using words like "beauty," "pleasure," "delightful," and "pretty." Although many of Herzig's (2002) mathematicians devoted substantial time and effort to their teaching, most of them described their goals for teaching to be to cleanly communicate the main ideas of the subject, rather than to share their vision or to lead students to an appreciation of the ideas. They primarily lecture, with a focus on teaching as telling students what they need to know. Not surprisingly, the students described courses in which little motivation was provided for mathematical ideas, connections among ideas were not explored or even provided, and the mathematical "big picture" was missing.

Little if any mathematics instruction includes consideration of mathematics' aesthetic properties. What would be the impact of mathematics instruction that focused on leading students to appreciate the aesthetic, emotional, personal side of mathematics, rather than just passing on the facts of mathematics? Is this important?

Fourth, while mathematics is often classified as one of the sciences, it also bears many similarities to the humanities. Mathematical *knowledge* is a lot like that of the physical and natural sciences (Becher, 1989), which is reflected in the view of many mathematicians that mathematics is an aspect of the real world, which they work to discover (Maddy, 1990; Steen, 1999). However, the nature of mathematical *work* is more like that of the humanities. In the sciences, students often have research experiences as undergraduates, and graduate students generally begin research early in graduate school, which is rarely the case in humanities (Golde, 1996; Tinto, 1993) or in mathematics, where students often don't begin research until they have completed their graduate coursework (National Research Council, 1992). Research in mathematics and the humanities is more likely to be individual and isolated (National Research Council, 1992), compared with a high degree of collaboration in the sciences (Becher, 1989; California Postsecondary Education Commission, 1990; Golde, 1996; Nerad & Cerny, 1993).

How would mathematics instruction look if the focus was on mathematics as one of the liberal arts, if we taught mathematics as one of the great works of human thought?

Mathematics is each of these things, at all points along these continua, in different contexts and at different times. In each of these ways, engaging in mathematics is a very varied activity. I will argue that the educational experiences of many students represent a much narrower range of activity than those that characterize the work of mathematicians. Although I am not trying to model the work of students directly after the work of mathematicians, I will argue that the ways in which we narrow mathematical activity for students limits their abilities to truly understand, appreciate, and use mathematics.

## STUDENT REASONING DURING IMPLEMENTATION OF TWO GENERALIZING TASKS: ASPECTS OF GENERALIZING AND THE ROLE OF REPRESENTATIONS

Megan Staples  
Stanford University  
mstaples@stanford.edu

This paper analyzes two lessons where students worked on generalizing tasks. Despite the similarities of the tasks and format of the classes, these two lessons proceeded quite differently. One lesson progressed smoothly and students produced and justified a generalized formula. In the second lesson, students encountered difficulties and the teacher had to heavily scaffold students' engagement with the task. Three distinct aspects of generalizing tasks (particular, formal, and contextual generalization) are discussed and the role of representations in mediating the interrelationships among these aspects of generalizing is considered. An understanding of these interrelationships has important implications for classroom instruction.

Recent work on task analysis and implementation has heightened our awareness of the role of tasks in structuring classroom interactions, and more specifically, how the demands of a task can shift during task implementation (Stein, Smith, Henningsen, & Silver, 2000). The analysis presented here contributes to this area of research by considering the evolution of student reasoning on generalizing tasks during two lessons. I consider how students' engagement with particular representations mediated their progress on the task as they moved between generating examples and generalizing.

The data for this paper are classroom videos collected as part of a yearlong study of a ninth grade Math A (pre-algebra) class. The videos were taken during a unit on patterns. Each lesson focused on a generalizing problem:

Lesson 1: How many diagonals are there in a polygon with  $n$  sides?

Lesson 2: How many ways can you arrange  $n$  different flavors of ice cream on a cone?

The goal of each task was to find and justify a general formula for the  $n$ th case. Despite similarities in the tasks and the instructional format, these two lessons proceeded quite differently. In the diagonals lesson, students' made steady progress. In the ice cream cone problem, students had more difficulty and the teacher had to heavily scaffold students' engagement with the task to keep a high level of cognitive demand. (See Staples, 2002 for further discussion.)

### A Closer Look at 'What It Takes' to Generalize

To understand the differences between these two lessons, it is useful to distinguish among different kinds of generalizing opportunities typically afforded by gen-

eralization tasks (Driscoll, 1999). I refer to these as *particular*, *formal*, and *contextual* generalizing<sup>1</sup>. A *particular generalization* is a pattern or rule by which any particular example could be generated (e.g. the next value in a sequence is two more than the last value). A *formal generalization* is a general rule expressed symbolically encompassing all cases at once (e.g.,  $y = 2(x-1)$ ). A *contextual generalization* is a general rule grounded in the context or problem situation (e.g., since all but one person in the park has a bike, the number of bike wheels is twice the number of people minus two). Contextual generalizations are often used to justify formal generalizations, and have been a focus of reform-oriented teaching. Although these aspects of generalizing do not have to be addressed in any particular order, and can be engaged simultaneously, often generalizing tasks are structured so students progress from the particular to formal to contextual. The assumption is that the thinking and reasoning students do to produce, for example, a particular generalization is a useful step on the way to a formal or contextual generalization.

### The Lessons

In the diagonals lesson students, under the guidance of the teacher, worked with the particular examples of a square, hexagon, and an octagon, finding the number of diagonals of each. The emphasis was on developing a systematic process of drawing and counting the diagonals. Remarkably, while working on the third example, several students articulated a formal generalization and then offered a contextual generalization, explaining how the formalization was connected to the geometry of the  $n$ -gons. Thus in this lesson there was a tight connection among the three different kinds of generalizing activities. Students' work with the three examples, and more specifically, their process of developing an increasingly systematic method for drawing diagonals, afforded students the opportunity to engage the three aspects of generalizing concurrently.

The ice cream scoops lesson unfolded quite differently. Students produced particular, formal and contextual generalizations as three distinct phases of the lesson. Using a table, students recognized and articulated a particular generalization: moving down the right column, values are multiplied by 2, 3, 4, etc.

| # of scoops | # of ways to arrange |
|-------------|----------------------|
| 1           | 1                    |
| 2           | 2                    |
| 3           | 6                    |
| 4           | 24                   |
| 5           | 120                  |

After producing this particular generalization, students were unable to make headway towards a formal or contextual generalization. Their engagement with the tabular representation, while amenable to a particular generalization, did not provide students with resources for the subsequent generalizing activities. The teacher had to actively scaffold their engagement with the problem, verbally directing their attention to features of the pattern (e.g.  $24=4 \times 3 \times 2$  not only  $4 \times 6$ ) and then employing both a visual and situational representation to help students complete the task. Thus during lesson, the different kinds of generalizing activities in this lesson were not closely linked or mutually supportive. One can imagine alternative approaches such that these generalizing activities would more closely align. Interestingly, the visual representation was not an adequate resource in this task implementation, perhaps because, unlike the diagonals lesson, attention was not given to its systematical production, and so did not provide students with the same kinds of experiences with the structure of the problem.

### Summary and Implications

This analysis highlights the importance of attending to the different kinds of generalizing (particular, formal, and contextual) required by a task, as well as the role of particular representations (tabular, visual, situational) in mediating the connections among them. A close connection among the three kinds of generalizing is assumed, but this relationship requires further consideration. The interrelationship among these depends upon task implementation and the affordances of the representation used. An understanding of the interrelationships and representations has implications for classroom instruction. In designing activities and planning instruction, teachers make choices about representations and whether to direct students to preferentially consider one kind of generalizing over others. These choices can significantly alter the progression of a lesson, the learning opportunities afforded students by a particular task, and the work the teacher must to support students in completing the task.

### Note

<sup>1</sup>Friedlander and Hershkowitz (1997) use the terms *working* and *explicit* generalizing for *particular* and *formal* generalizing.

## **BUILDING A FRAMEWORK TO ANALYZE STUDENTS' SUPPORT NETWORKS FOR THEIR MATHEMATICS EDUCATION**

Susana Davidenko  
SUNY Cortland  
davidenko@cortland.edu

This paper proposes a framework for analyzing the support networks that students develop when interacting within the embedded contexts of the mathematics classroom, the school, and the community. Instead of looking at the networks within each of these settings, we look at the *type* of support provided to the students. We focus on academic support in mathematics from a broader point of view, including experiences inside and outside the mathematics classroom that may have a great impact on a student's attitude towards mathematics and his/her understanding of mathematics. The framework also proposes to look at all sites where students are exposed to mathematics instruction through the lens of a constructivist approach to learning.

### **Defining the Framework**

The ideas proposed here have emerged from a larger qualitative research (the author's dissertation study). Some of the questions guiding the study are: what experiences in- and out-side the school help English-Language-Learners (ELL) make sense of mathematics when they take English-taught mathematics classes? What circumstances seem to hinder these students' advancement in mathematics? (Note that although these questions were originally designed to explore ELL students' experiences, the results included in the current paper are not limited to ELL students. Specific results related to ELL issues are not presented in this paper.) The original study took place in an innercity high school, within a poor community in New York State. Minority students compose approximately the 50% of the school population--African-American 36%, Latino 9%, and Vietnamese 4%. The English as a Second Language (ESL) program—a combination of ESL classes and ESL push-in strategies—serves 10% of the school population. To better understand students' experiences, the data collection included observations in two algebra classes, and a series of interviews with the algebra teachers, eight students from those algebra classes, a Latino vice-principal, an ESL teacher who pushed into one of the algebra classes, a special education assistant who pushed into the other algebra class, and a Latino ESL teacher assistant. The interviewed students were ELL and non-ELL, male and female students. Latino students were from Puerto Rican (4) and Mexican (2) backgrounds.

Although most students received the core of their mathematics instruction in their algebra classrooms, data from the study revealed that each student had a variety of experiences that he/she perceived to have a significant impact on his/her motivation towards school and higher education, and on his/her actual opportunities for learning mathematics meaningfully.

Listening to the student voices allowed for the creation of categories of relationships based on the *nature of the support* provided to the students. A relationship may provide (#1) *Affective*, (#2) *Academic*, (#3) *English*, and/or (#4) *Social and Cultural support*. Instead of looking at students' relationships within a classroom, school, or community settings, we look *across* these contexts to uncover the relationships that impact students' learning of mathematics. The emerging framework proposes the definition of a *student's support network* as the structure of all students' interpersonal relationships, the student's participation in social and cultural organizations, the student's utilization of resources, and any other relationship that provides the student with some type of support for his/her education. As relationships change, develop, or end, support networks are to be considered dynamic structures.

This framework emerged from the data and was used, later on, to reflect back on the data about students' experiences. Following are some examples: (a) we expect *academic support* from the algebra teachers, but the data showed that the drill-and-practice approach to teaching algebra generated students' frustration, for lack of understanding. The teachers did not provide true academic support but actually hindered the students' mathematical thinking; (b) the ESL teacher greatly helped ELL students to learn English and adjust to the American culture (#3 and #4). ELL students also consulted her for affective support (#1) and for tutoring in mathematics. As she taught her students in a step-by-step, memorization fashion, she did not succeed in providing proper academic support in mathematics; (c) A sport coach became an affective support (#1) for a Puerto Rican student who played in his team, as well as a support for learning English through the reading and discussing sport magazines.

The proposed framework could be used by practitioners and researchers in other situations; for example, to understand and explore support networks of students with special needs, defining categories of support that might be crucial in these students' inclusion and success in their academic career.

## MATHEMATICS AND THE MEME

Timothy Gutmann  
University of New England  
gryphon@phrost.mv.com

In *The Selfish Gene*, Richard Dawkins (1976) introduced a gene-centric view of the history of life. Genes are self-replicating units whose essence (the biological instructions they encode) persists indefinitely (possibly with minor transmission errors); thus in Dawkins's theory genes, rather than individuals or species are seen as the basic units of life and evolution. A key point of Dawkins's thesis is this: any immortal, self-replicating, possibly erring entity in an environment of limited resources will be subject to the laws of Darwinian evolution. It is the inevitability of Darwinian processes that leads in Dawkins's final chapter to an enticing application of the theory, one with important implications for mathematics educators as we think of knowledge as culturally situated and generated.

Dawkins's new application is the *meme*. A gene is a unit of biological information; a meme is a unit of cultural information. It might be a catchy tune or remarriage taboo. It is a thought that replicates by passing from one mind to another. Other criteria are satisfied and the principles of Darwinian evolution govern how memes spread (for a thorough introduction to the study of the spread of memes, see Lynch, 1996).

PMENA XXII spotlighted socio-cultural issues in mathematics education. Several researchers speak of knowledge as culturally held and generated. Attention to the theory of memes provides a mechanism for this process and a point of view leading us to ask new kinds of questions about mathematics learning.

### A Mechanism

Knowledge is culturally held and generated. What does that mean? How does it occur? One answer is theories of enculturation (for recent applications see, Gutmann, 2000; Tirenay & Rhoades 1994). Here the agent is the cultural group, initiating newcomers to traditions and knowledge. Memetics suggests a different point of view: meme-centric. Memes, cultural ideas are independent actors working to perpetuate themselves by infecting new minds. If one adopts this point of view, then one must concurrently adopt a radically different stance to understanding learning. Rather than minds acquiring or constructing knowledge or cultural competencies, knowledge and cultural competencies acquire and construct minds. The task of the teacher is not to help students learn, but to help students become more receptive vessels for memes.

### New Questions

Several have attempted to answer "what is mathematics?". Most have focused on what its tools are, what its modes of thought are, and what its applications are. If instead we ask "what is the mathematical meme complex?" "What are the cultural

units that combine to create a being called mathematics that as a whole perpetuates its component memes?" then we ask a new breed of question. For example, we might observe that western mathematics has often been thought of as the province of the elite. We should now ask why it aids the mathematical meme complex, aids in an evolutionary sense, a self-perpetuation sense, to be restricted to only a few, elite minds. We should begin to ask not only "what is mathematics?", but "what is the environment that has fostered the evolution of the mathematical meme complex?"

The purpose of the poster is to introduce these ideas and generate discussion. Memetics as a science has developed and changed with many of Dawkins's ideas being alternatively lauded or abused in different camps. My own thoughts on this subject are only beginning to gel, but my sense is that a meme-centric view of mathematics learning can provide a language to describe learning in the classroom, one which focuses on the development of knowledge through social interactions within a community of learners. As mathematics educators take up a cultural lens with increasing frequency, new mechanisms need new languages to describe them and introduce new kinds of questions.

## EXPOSITORY WRITING AND COMMUNICATION IN GRAPHING LINES

Drew K. Ishii  
The Ohio State University  
ishii.11@osu.edu

Susan L. Kline  
The Ohio State University  
kline.48@osu.edu

In response to the proposal of *Principles and Standards* (National Council of Teachers of Mathematics, 2000) that communication be an integral part of the mathematics classroom, we have developed a conceptual framework from which to understand students' expository communication activities. Little attention has been paid to understanding the way communication processes, interaction practices, and functional exposition elements are integrated in expository communication. This general framework is an effort toward understanding the nature of communication in the mathematics classroom. This study initiates the understanding of communication with this framework and explores its utility for identifying the explanatory communication practices of undergraduate remedial mathematics students' expository writing. We explore how each of these communication activities may be realized and enacted in particular explanations of mathematical concepts and processes. We also examine the extent to which these communication activities are related to others' assessments of student writing.

Expository writing in the mathematics classroom engages students in writing as an active part of the learning process and classroom instruction. This writing allows students to catch mistakes in addition to remembering and understanding problems better (Cai, Jakabcsin & Lane, 1996; Drake & Amspaugh, 1994). The natural process of writing requires students to reflect upon their thoughts before solidifying them into words. This process makes their thoughts objects of further thought. Powell and Lopez (1989) describe learning as a dynamic process where students move between experiences and reflections. Somewhere between the experiences and the reflections, students go through critical reflections. Bell and Bell (1985) first discovered that there was a link between writing and the mathematical thinking behind problem solving.

In order to develop our framework, we incorporate classic views on the role of logic in teaching (Ennis, 1969), the current work on expository writing and communication, including the studies mentioned above (Schoenfeld, 1998), technical writing (Wieringa, Moore, & Barnes, 1992), as well as work in communication and discourse analysis that has been focused on the analysis of explanations and explanatory discourse (e.g., Antaki, 1981; Garfinkel, 1981). Together with this literature, research in mathematics education, and our data analysis, we suggest that the following categories of communication activities are present in expository writing in mathematics instruction: orienteering, articulating relevant concepts, legitimizing concepts, stating connections between the concepts and their features, guiding procedural activity, solidifying conceptual understanding, and facilitating linguistic control.

Orienteering is structuring the interaction or guiding the reader's attention and displaying awareness of the informative activity. Articulating relevant concepts with interpretive explanations is providing the reader with a kernel. Legitimizing concepts through reason-giving explanations is using models to display the procedure or concept and provide concrete interpretation with exemplars or displays. Stating connections between the concepts and their features is reasoning and providing coherence with exemplars in procedures. Guiding procedural activity with descriptive explanation is explaining the relevant process or procedure. Solidifying conceptual understanding is making discursive connections to help solidify new knowledge and create elaborative connections. Finally, facilitating linguistic control is the use of mathematical terminology and specific language.

**EQUITY IN THE MATHEMATICS CLASSROOM: A STUDY OF THE  
CONNECTION BETWEEN PRE-COLLEGE EXPERIENCES AND  
MATHEMATICS ATTITUDES OF UNDERGRADUATE  
AFRICAN AMERICAN STUDENTS**

Shonda Lemons-Smith  
Fort Valley State University  
Lemons-s@mail.fvsu.edu

This study examined how pre-college experiences with equity in the mathematics classroom connect to mathematics attitudes in undergraduate African American students. Specifically, from the perspective of selected African American undergraduate students:

- (a) To what extent did the mathematics curriculum use contexts that were inclusive of a wide range of student experiences and perspectives?
- (b) To what extent did mathematics instruction incorporate and value diverse student experiences, perspectives, and learning styles?
- (c) To what extent did the classroom culture promote positive teacher-student and student-student interaction and relationships?
- (d) How are mathematics classroom experiences connected to one's feelings toward mathematics?
- (e) How are mathematics classroom experiences connected to one's feelings about oneself as a learner of mathematics?

In the study attitudes was defined as feelings about mathematics and feelings about oneself as a learner of mathematics. Equity was defined as the idea that all students, regardless of their race, ethnicity, gender, social class, or other cultural characteristics should have equal educational experiences that support equal achievement. Equity in the mathematics classroom was examined from three aspects: curriculum, instruction, and classroom culture.

The study found that pre-college experiences with equity are integrally connected to the mathematics attitudes of African American undergraduate students in that the kind of mathematics experiences they had either encouraged or diminished positive attitudes toward mathematics and toward themselves as learners of mathematics. How those experiences affected attitudes were influenced by teacher characteristics (the type of math teachers the student encountered), student resiliency (personality and other individual traits), and student ideology (how the student viewed himself and the world).

## GROWTH OF MATHEMATICAL UNDERSTANDING IN A BILINGUAL CONTEXT: A CASE STUDY OF TONGAN SECONDARY STUDENTS

Sitaniselao Stan Manu  
University of British Columbia  
ssmanu@interchange.ubc.ca

The National Council of Teachers of Mathematics in the *Curriculum and Evaluation Standards for School Mathematics* (1989) addressed the issues concerning bilingual students' learning of mathematics by announcing that "students whose primary language is not the language of instruction have unique needs" (p. 142). This lack of proficiency in the language of instruction often leads these bilingual students to switch languages (Fasi, 1999) partly because learning mathematics *in* and *through* a second language presents a double challenge – learning of mathematics and the need to understand the language of instruction (Adler, 1998). My experience as a mathematics educator with a bilingual background has allowed me to study the relationship between bilingual (Tongan) students' "language-switching" and their growing mathematical understanding. My research interests centered on "What is the relationship between Tongan bilingual students' *language-switching* and their *growth of mathematical understanding*?"

### Theoretical Framework

The Pirie-Kieren dynamical theory for the growth of mathematical understanding offers a *language* for explaining, and way of observing, the dynamical growth of mathematical understanding. Pirie and Kieren (1991) explicitly state that growth of understanding occurs through a continuing movement back and forth between the layers or modes of understanding to re-member and to re-construct new understanding, recognizing the inter-dependence of all the participants in an environment. Standard distinctions within systemic functional discourse analysis, based on Halliday's work (1978), are employed to understand the data better in making the link between *theory/practice* and *action/reflection* (general or specific) as an essential step in enriching one's analysis of video data particularly in this context about how each layer of the Pirie-Kieren Model has a basis in the discourse. Its importance for understanding the role of language (either English or Tongan) in teaching and learning is crucial.

### Method and Tasks

Grades 8 and 9 Tongan students were asked to solve mathematical tasks together in pairs or threes. Video was employed to capture both the verbal and non-verbal evidences of these students' growing understanding of fractions and patterns and relations. The videotapes form the main data of the study, although they are supplemented with audiotapes, field notes, written work and any appropriate record of the

students' work together with *video-stimulated recall* to clarify and to elaborate what was observed. Bilingual students' growth of mathematical understanding will be analysed and mapped using the Pirie-Kieren diagrammatical model in terms of their uses of images (mostly at the *image*-layers) and the relationship between their *language-switching* and the Pirie-Kieren's notion of *folding back*.

### Findings and Conclusion

In doing the assigned tasks, the Tongan students appeared to work mostly at the *image*-layers, either working with their constructed images at the *image having* and *property noticing layers* or constructing new images at the *image making layer*. In addition, the concept of *reflection* resembles that of Pirie-Kieren's notion of *folding back*, and this similarity requires further investigation. Through the framework of the Pirie-Kieren Theory, the systemic functional discourse analysis has offered a thorough understanding of the comprehensive meanings of the bilingual students' language use. Halliday (1978) suggests that since languages "differ in their meanings, and in their structure and vocabulary, they may also differ in their paths towards mathematics, and in the ways in which mathematical concepts can most effectively be taught" (p. 204). As a result, bilingual students might pay attention to different characteristic of a particular language and further research could be done to explore if ESL students create new pathways towards understanding mathematics.

## PROJECT VOICE: LISTENING TO AFRICAN-AMERICAN STUDENTS' VOICES ABOUT THEIR MATHEMATICAL EXPERIENCES

Vivian R. Moody  
The University of Alabama  
vmood@bamaed.ua.edu

This poster session highlights the findings and implications of the research project, *Project Voice: Listening to African-American Students' Voices About Their Mathematical Experiences* (Research Advisory Committee Grant No. 2-67968, The University of Alabama). The project used the metaphor of *voice* to investigate the mathematical experiences of four (two males and two females) African-American students. The primary goal of the project was to give voice to African-American students who had been successful with school mathematics to determine what factors led to their success. The data suggest that teachers and particular teaching practices are paramount in fostering successful African-American mathematics students.

"Voice refers to the discourse that is created when people define their own issues in their own ways, from their own perspectives, using their own terms—in a word, speak for themselves" (Secada, 1995, p. 156). Using the *voice* metaphor as the basis of this investigation, this project examined the mathematical experiences of four African-American students to determine what factors led to their succeeding in mathematics. The project particularly investigated the African-American mathematics students' perceptions of and responses to their mathematics education and sought to unravel whether experiences in mathematics classrooms shape African-American students' viewpoints about their mathematical experiences and inevitably impact their succeeding in mathematics.

The research project employed a phenomenological research strategy. Phenomenology is the study of lived experiences and essences that allow researchers to discover that, which makes an experience unique and meaningful for an individual. Further, phenomenology is aimed at interpretive understanding and describes subjective experience from the viewpoint of the individual (Tesch, 1987). The study particularly examined the phenomenon of being a successful African-American mathematics student from the viewpoint of the student.

Data were collected in the form of an initial survey, an autobiography, and interviews, including a third and final interview that consisted of a member-check by the participants. The initial survey was a questionnaire that consisted of open-ended questions. The participants were asked to describe the schools they attended from elementary school throughout college. They were asked to provide descriptions in their own words of these schools, the mathematics courses they took, their mathematics teachers, and the mathematics classrooms in which they participated. For the autobiography, the participants were asked to write a story of their lives as successful

African-American mathematics students in the schools and mathematics classrooms they had described in the initial survey. They were given no instructions on how to write their stories but were asked to describe their interactions with mathematics teachers, peers, and other persons who were important in the telling of their stories. The participants were interviewed three times: once, after the completion of the initial survey, secondly, after the completion of the autobiography, and a third time toward the end of the study.

The results of the study suggest a need to prepare teachers to become *culturally responsive teachers* (Malloy, 1997). "Culturally responsive mathematics pedagogy is predicated on the teacher's interpreting, understanding, and recognizing the students' culture and integrating it into the learning process [and] the teacher's allowing students to construct mathematical knowledge on the basis of their experiences " (Malloy, 1997, p. 28). The results also suggest a need to prepare teachers to become what the participants called *caring educators* who listen to African-American students' voices and endorse their preferred ways of learning mathematics. Finally, the data suggest a need to reconstruct mathematics teacher education programs that raise the critical social consciousness of preservice teachers and help them reflect on the nature of structural oppression as it affects African-American mathematics students. Such reflection has the propensity to help teachers embellish teaching practices that embody equity and counter oppression, which ultimately fosters successful African-American mathematics students.

## STUDENTS' EXPERIENCES WITH COOPERATIVE LEARNING

Lisa Sheehy

North Georgia College and State University

lsheehy44@yahoo.com

Johnson & Johnson (1991) classify the structure of general classroom instruction in three main forms: competitive, cooperative, and individualistic. They claim that "for the past fifty years competitive and individualistic efforts have dominated classrooms" and that "cooperative learning has been relatively ignored and underutilized by teachers even though it is by far the most important and powerful way to structure learning situations" (p. 26). For the past twelve years, as a teacher of both secondary mathematics students and pre-service teachers, I have incorporated cooperative learning into my lesson structures and have found myself continually challenged to answer the question: What is meant by this "way" called cooperative learning as it relates to mathematical learning?

Cooperative learning has been widely researched from a variety of perspectives. Researchers have shown that cooperative learning can result in positive effects on students' achievement, motivation, self-esteem, and race-relations (Rottier, 1991; Bellanca & Fogarty, 1991; Kluge, 1990). With a focus more on process than outcome or effect, researchers have investigated students' interactions (Webb, 1991), questions (Walter, 2001), and cognitive processes (Appleton, 1997). An aspect of cooperative learning that has received limited focus in previous research is students' experiences with cooperative learning from their own individual perspectives.

Believing there is a need to provide students' a voice in this research, I conducted an interpretative study in which I observed and interviewed three female, pre-service secondary mathematics teachers. The goal of the study was to investigate the ways in which the students were both simultaneously constructed and constructed by cooperative learning experiences as they engaged in mathematical problem solving. Emphasis during analysis focused on how are these various constructions are related to the students' mathematical activity.

Data was collected as the participants worked cooperatively, on three separate occasions, to solve different mathematical problems. Each problem solving session (PSS) was immediately followed by a group interview in which the participants discussed their perspectives on the PSS. The following day each participant returned for an individual, 90-minute interview where she and I viewed the tape together—pausing often to discuss specific instances pointed to by both myself and the participant. In light of the employed methodology coupled and my belief that we do research with and not on people, the participants were, in a strong sense, co-researchers. They participated in data analysis (by analyzing videotape as they viewed it) and helped for-

multate discussions and interview protocols (by using the group interviews to identify themes in their own conversations).

St. Pierre and Pillow (2000) claim that "the work and challenge of postmodern theory is to continually question our "taken-for-granted structures of intelligibility." The participants in this study feel that they had the opportunity to question and deconstruct some traditions of cooperative learning. They also feel that they were able to reconstruct what cooperative learning is for them as learners and what it will be for them as teachers. One of the participants will join me in this poster session as we view and discuss 30-second video clips that highlight salient aspects of the research findings with the conference attendees. This will be a unique opportunity for attendees to interact with one of the study participants and to hear about her interpretations of and experiences with cooperative learning.

## FOSTERING CLASSROOM DISCOURSE THAT HELPS STUDENTS LEARN AXIOMATIC GEOMETRY

Draga Vidakovic  
Georgia State University  
draga@gsu.edu

As we move into the new century, efforts to enhance school mathematics teaching and learning continue. Within the last decade, many researchers have focused on studying pre-service/in-service teachers' content and pedagogical knowledge. The results of such research made us aware of various difficulties and issues that affect instruction and students' learning. Researchers focusing on classroom discourse point out that teacher's content and pedagogical knowledge influence the richness of class discussion, teacher's instructional style, and student learning (Fennema & Franke, 1992; Knuth & Peressini, 2001). Furthermore, Marks (1990) emphasizes the importance of links of teachers' content and pedagogical knowledge.

In this presentation the author will describe a specific activity identified by the participants of the study as the most valuable for creating mathematical discourse in a college level geometry course. The study represents an attempt to apply and extend the results of research done at the K-12 level. Sixteen students, mathematics and mathematics education majors, enrolled in the 'Euclidean and Non-Euclidean Geometry' course at the large Southeastern American University participated in the study. The course was structured and designed with the intention to put into practice recommendation stated in the National Council of Teachers of Mathematics (1991) -- using various pedagogical methods to engage students actively in the process of teaching and learning of mathematics. In particular, the report will focus on discourse in which students engage as they present in class their solutions to homework assignments. Data collected throughout the semester that will be used for this particular presentation consists of students' journals and video recorded class presentations.

The results of the investigation suggest that dialogical discourse that appeared between student-presenter and his/her classmates was the most powerful and helpful in developing their understandings about those "propositions and axioms that continue to hunt" them. As it could be seen from the videotaped classroom sessions (and confirmed in students journals) students created productive mathematical dialog by questioning and challenging each other to defend their answers. The classroom climate was encouraging for students to 'take risks'. All of them were very involved and responsive. Even when a question appeared trivial, no one ridiculed anybody's thinking. Through active involvement and participation the students developed understanding and acquired knowledge. Detailed analysis of components of such discourse will be presented.

## TEACHER IDENTITY AND KNOWLEDGE IN ELEMENTARY MATHEMATICS<sup>1</sup>

|                                  |                                      |                                  |

Research shows teacher thinking is influenced by both knowledge and identity. Yet these two constructs are rarely studied in combination. This study documents the knowledge and identity of teachers experienced in mathematics reform, and examines how identity and knowledge resources interact in teachers' thinking about instruction. We interviewed eight teachers involved in either Investigations in Number, Data, and Space or Cognitively Guided Instruction. We found teachers' knowledge of multidigit multiplication and division generally exceeded that of teachers in prior studies, and they held uniformly positive perceptions of their current identities as learners and teachers of mathematics. Furthermore, teachers' high point and/or turning point experiences were closely linked to their conceptions about how to foster understanding in students. Low-point experiences for teachers with early negative stories framed current conceptions about the role of affect in understanding. Two cases illustrating specific links between knowledge and identity themes are presented.

A great deal of attention has been devoted to understanding elementary teachers' knowledge of mathematics and children's mathematical thinking in the context of standards-based instruction (Ball, Lubienski, & Mewborn, 2002). A separate line of work, equally robust, has investigated teacher identity and its influence on teachers' understanding of practice (Carter & Doyle, 1996; Clandinin & Connelly, 2000). With increasing pressure for education reform one unanswered question concerns how knowledge and identities *interact* and *change* over teachers' lives, and what can be done to facilitate change in the directions valued by many in the education community—toward, for example, more student-centered instruction that includes problem solving and constructing mathematical arguments. Although these questions have been pursued separately for knowledge and identity, we believe mathematics education reform can profit from the study of the two constructs in combination.

### Framework

We focus on *narratively organized* identity (Bruner, 1990; Drake, under review), or the stories teachers tell about themselves and their experiences, the meanings they give to their experiences, and the narrative coherence they see across their past, present and future professional lives. Teachers use these personal narratives to “define what is recognized as significant in the stream of experience” and to “stipulate how issues and problems can be thought about” (Carter & Doyle, 1996, p. 134). In contrast, teachers'

knowledge is usually depicted using *conceptually organized* frameworks representing the aspects of mathematics and children's thinking most salient for instructional decision making (e.g., Franke, Carpenter, Levi, & Fennema, 2001; Ma, 1999).

Bruner (1996) argues that "interpretations of meaning"—such as what to make of a child's unusual invented strategy—"reflect not only the idiosyncratic histories of individuals, but also the [sub]culture's canonical ways of constructing reality" (p. 14). Teachers' understanding thus depends on meanings rooted in their own stories and on those reflecting culturally shared knowledge of mathematics and children's thinking—such as the knowledge teachers may hold as a community by virtue of participating in the same reform agenda. Teacher thinking is influenced by narrative *and* conceptual perspectives, reflecting individual and communal histories.

This framework leads us to expect teachers to use both identity and knowledge resources to make sense of a variety of issues central to their practice. For this paper we focus on an issue that has figured prominently in calls for reform: understanding mathematics. Virtually all teachers involved in reform are committed to helping students understand the mathematics they teach. But beyond this basic commitment, teachers differ in their thinking about what understanding is, its sources, how it develops, its affective components, and so on. These differences are reflected in teachers' instructional practices, and ultimately, we believe, in student outcomes.

### Question

Our goals in this paper are to: 1) examine reform-oriented teachers' knowledge and identity, and 2) identify how identity and knowledge resources influence teachers' thinking about reform-oriented instruction, with specific regard to facilitating students' understanding of mathematics. Building on the premise that narrative is a powerful tool for organizing new information, Drake (under review) has established that teachers' stories influence their initial experiences of reform. Our question is, as teachers become experienced at reform teaching, how does their knowledge of mathematics and children's thinking influence their identities as mathematics teachers? And how do teachers' newly recast identities motivate new knowledge? We conjectured that as domain-specific knowledge of mathematics or children's thinking increases, teachers may reconsider or "re-write" their identity stories, and the role of earlier mathematics identities as resources for interpreting practice would shift.

### Method and Data Sources

We analyzed the knowledge and identity of eight teachers of grades 3-6 involved in mathematics reform in two low-income urban settings. We chose schools with different reform-oriented approaches to mathematics instruction to achieve a range in teacher knowledge and story type. One school was located in Austin, Texas, and had been implementing *Investigations in Number, Data, and Space* (TERC, 1995-1998) for five years. Over 80% of its students came from low-income families. The school

population was classified as 11% African American, 75% Hispanic, 12% White, and 20% Limited English Proficient. The other school was located in Phoenix, Arizona; teachers had been implementing Cognitively Guided Instruction (CGI) (Carpenter, Fennema, Levi, & Empson, 1999) for three-six years. Virtually 100% of its children came from low-income Latino families. All of the teachers from this school worked in bilingual classrooms. Teachers were given pseudonyms beginning with 'I' (for *Investigations*) or 'C' (for CGI).

### Instruments

Each teacher participated in 1) a mathematics story interview designed to elicit teachers' mathematics *identities*, and 2) a teaching-scenarios interview designed to elicit *knowledge* of the domain and student thinking in multidigit multiplication and division. The Identity Interview included questions about teachers' high points, low points, and turning points in learning and teaching mathematics, for which teachers were asked to describe the setting, what happened, who was involved, and feelings brought on by the event. The Knowledge Interview included scenarios of students' correct and incorrect invented algorithms for multidigit multiplication and division, questions about the relative roles of invented and standard algorithms in the development of understanding of multidigit operations, and questions about particular students and their mathematics understanding (Table 1).

### Coding/Analysis

We began by analyzing the knowledge and identity interviews separately. We then coded across each teacher's two interviews for evidence of their conceptions about sources of understanding (self, community of peers, teacher/knowledgeable other, materials), and mechanisms for developing/acquiring understanding (sample codes include: inventing strategies, interacting with others' thinking, use/application, making connections, exposure to multiple strategies, "seeing"/visualizing, persistence/effort, being told/shown, "it just clicks"). The codes were derived from multiple passes through the data and our knowledge of the literature on mathematics understanding (e.g., Carpenter & Lehrer, 1999). After coding each teacher, we looked for patterns within and across teachers, and generated portraits of each teacher's conceptions about mathematics understanding.

### Results and Discussion

We first present findings related to the separate analyses of knowledge and identity interviews. We then consider how different combinations of knowledge elements and identity experiences result in different portraits of teachers' thinking about what it means to understand mathematics, and present two cases illustrating these findings.

Table 1. Selected Items From Knowledge Interview

| (Item order) type  | Item   |
|--|--|
| <p>(2) Multidigit <math>\div</math>:</p> <p>Novel invented strategy with misconception</p> | <p><i>Lucia was solving <math>144 \div 8</math>. She said, "I know, I can just split it in half. So I will keep dividing by 2. I need to do that 4 times, since <math>2+2+2+2</math> is 8. The answer is 9." As she talked, she wrote this (indicate written strategy). How would you respond to Lucia?</i></p> $  \begin{array}{r}  144 \\  \div 2 \\  \hline  72 \\  \div 2 \\  \hline  36 \\  \div 2 \\  \hline  18 \\  \div 2 \\  \hline  9  \end{array}  $  |
| <p>(3) Multidigit X:</p> <p>Common invented strategy</p>                                   | <p><i>You have given your class a problem that involves figuring 24 groups of 32. James is the first child to share his strategy with the class. He figured 24 groups of 32 using this strategy:</i></p> $  \begin{array}{r}  32 \\  +32 \\  \hline  64 \\  +32 \\  \hline  160  \end{array}  \qquad  \begin{array}{r}  32 \\  32 \\  32 \\  32 \\  +32 \\  \hline  160  \end{array}  \qquad  \begin{array}{r}  160 \\  160 \\  160 \\  +160 \\  \hline  640 \\  +32 \\  \hline  672 \\  +32 \\  \hline  704 \\  +64 \\  \hline  768  \end{array}  $ <p><i>What do you learn about James through this strategy? As James explains his strategy to the class, what questions would you want to ask James or the other children about this strategy? What kind of strategy would you want a child to share next?</i></p> |
| <p>(5) Multidigit X:</p> <p>Common misconception</p>                                       | <p><i>You have given your students the problem <math>27 \times 42</math> to solve. Julia says to you, "Simple. <math>20 \times 40</math> is 800. <math>7 \times 2</math> is 14. So it's 814" You know this strategy is incorrect. How do you respond to Julia? When it is time for your students to share and discuss strategies, would you have Julia share her strategy with other students? Why or why not? (Strategy from Ambrose, Baek, &amp; Carpenter, in press.)</i></p> <p>Show card with:</p> $  \begin{array}{r}  20 \times 40 = 800 \\  + 7 \times 2 = 14 \\  \hline  814  \end{array}  $  |

### Teachers' Knowledge

Every teacher but one, Ms. Ibenez, was able to generate at least two invented strategies (i.e., nonstandard strategies using base-ten concepts and algebraic principles) beyond repeated addition for double-digit multiplication.

All teachers found the novel division strategy with a misconception (Table 1, item 2) difficult to understand, and only one teacher, Ms. Carranza, identified the nature of Lucia's misconception as involving an additive decomposition of the divisor instead of a multiplicative one. There were differences, however, between the *Investigations* and CGI teachers in their hypothesized responses to Lucia. With the exception of Ms. Ives, *Investigations* teachers interpreted the division in quotative terms (the number of groups of 8), instead of partitive terms (the number in 8 groups), on which Lucia's strategy was based. For example, Ms. Ingold said Lucia should be thinking in terms of how many eights are in 144. Two teachers believed operating on the partial quotients (i.e., 72, 36, 18) could not lead to a correct strategy because "this part [half] is still left here, and you're only breaking up half" each time. Three out of four of the *Investigations* teachers reported they would redirect the student to use a strategy discussed in class. Ms. Ives, however, thought the strategy was "clever," and noted that the first two steps of repeated halving created four groups (but did not follow through on this reasoning to explain how eight groups could be created). In contrast, three of the four CGI teachers reported they had seen unusual invented strategies before, and all four recognized their confusion over this one, but wanted to explore it with Lucia rather than redirect her.

All teachers understood and could explain the common invented strategy for multidigit multiplication (Table 1, item 3). They differed in their knowledge of its placement in a developmental progression, and in their interpretations of what it signified about James's understanding. Ms. Immendorf and Ms. Ibenez believed James seemed confused; Ms. Ibenez noted that "sometimes he doubts himself and sometimes he's not sure" because he used smaller "clumps" when he could have used larger ones; she wanted to show him a more efficient strategy. In contrast, Ms. Cabrera and Ms. Cortez believed James's strategy was relatively sophisticated. Both teachers described less advanced strategies, such as repeated addition or using base-ten blocks, and more advanced strategies, such as a partial products approach; and explained how James's strategy could be part of a developmental progression. Ms. Carranza believed that, because of the different-sized chunks, the strategy was complicated to explain; James would have trouble explaining it to the class, and other children would have trouble understanding it.

Teachers differed in their understanding of Julia's strategy for multiplying two-digit numbers using a common misconception (erroneous generalization from two-digit addition where one operates on the tens and ones separately, and combines the results; Table 1, item 5). Three out of four *Investigations* teachers did not think it was

possible to multiply the tens and ones separately as viable first steps in a strategy. Ms. Ingold reported, "I would tell her that she's off to a good start, but that she can't break down both numbers, because that changes the meaning of the problem." Three out of four CGI teachers understood the partial nature of Julia's strategy, and reported they would ask her for a second strategy, or have her present her strategy to the class as a way to prompt the four partial products needed for the strategy to work (the fourth teacher was not given the item because she taught lower grades). Ms. Cabrera in particular expressed strong feelings about not showing Julia a correct strategy, because "it shouldn't have to be the way that I do it or the way that I was taught."

In summary, teachers' knowledge of multidigit multiplication generally exceeded that of U.S. teachers in prior studies (NCRTL, 1992; Ma, 1999). All teachers understood multidigit multiplication strategies other than the standard algorithm, and at least half the teachers understood these strategies at a deep level—that is, they could generate novel strategies, place strategies in a developmental progression, and/or make connections between different strategies. Some teachers' understanding of multidigit multiplication appeared limited to a few alternative strategies (such as the clusters approach in *Investigations*), which they did not readily generalize or connect to other versions (such as Julia's misconception). Other differences had to do with their hypothesized pedagogical responses to the students in the scenarios; we return to these themes later.

### Teacher Identity

In earlier research, Drake (under review) found teachers' math stories could be categorized based on *early (pre-adulthood) experiences* and *current perceptions*. Teachers' *early experiences* were either 1) negative, with very few recollections of positive events and/or at least one highly specific memory of failure in mathematics, or 2) mixed positive and negative, with positive memories as prevalent or more so than negative ones. In a sample of 20 teachers in their first year of implementing a reform-oriented curriculum, half of the stories were classified as negative, while half were mixed positive and negative (Drake, under review). Similarly, *current perceptions* were categorized as 1) positive about self as a learner of both mathematics content and pedagogy, 2) positive about self as learner only of pedagogy, or 3) negative about self as a learner of content. Almost half of the teachers, 9 out of 20, were in the first category, another 9 out of 20 were in the second category, and 2 out of the 20 were in the third category.

In the current study, all 8 of the teachers were positive about their current identities as learners of mathematics content *and* pedagogy. When discussing key events in their adult experiences as learners and teachers of mathematics, all 8 of these teachers described themselves as learning specific mathematics content as well as learning more generic pedagogical strategies. This consistent focus on mathematics content, in particular, across all the teachers is a stark contrast from earlier research on teachers new

to reform, of whom just under half had positive identities as learners of mathematics content. However, this group of teachers experienced with reform was similar to the earlier group of reform novices in that 3 of the 8 teachers (Ms. Immendorf, Ms. Ibenez, and Ms. Carranza) described primarily negative early experiences with mathematics, including at least one instance of failure, while the rest of the teachers described mixed early experiences. For all 8 teachers, their experiences with *Investigations* or CGI figured prominently in their descriptions of their high points and turning points.

Teachers' high-point and/or turning-point experiences were expressed through one of two kinds of story frames. One story frame focused on the excitement of understanding a piece of mathematics for the first time. These experiences usually came in adulthood, after prolonged experience of a different kind of mathematics (as non-sensical, rule-based, failure inducing). The setting usually involved knowledgeable others using concrete materials or multiple representations to express mathematics concepts and strategies. There is a sense of surprise at the possibility of understanding and newfound power to make and see mathematical connections. The second story frame involved teachers' sense of agency in effecting change in students' or colleagues' understanding of mathematics or self-perceptions as learners/teachers of mathematics. There is an emphasis on the power of helping others realize their inherent mathematical potential.

The low points teachers described in their stories generally occurred early, before or during college. While all of these low points depict scenes of struggle, frustration, and often failure, they, like the high points and turning points, were framed in one of two ways. In some stories, teachers' struggles and frustrations were similar to mental blocks; there was no clear reason for it, it just happened. Teachers who framed their low points in this way made blanket statements like, "I just never really understood" to describe entire experiences. Other teachers, however, had developed clear and specific reasons for their low points, often attributing them to the failure of knowledgeable others (teachers, parents, the school system) to provide the kind or level of understanding the teachers sought. These teachers said things like, "I wanted to know why things worked in math the way that they did. And somehow the teachers just never could quite explain it." There is a sense in these recollections that teachers have developed explanations for them in order to avoid repeating these failures with their own students.

### **Influence of Knowledge and Identity on Teachers' Thinking About Mathematics Understanding**

#### **General Findings**

Regardless of early mathematics learning experiences, CGI teachers expressed stronger beliefs in children's fundamental ability to create mathematics. Ms. Cabrera's case, described below, illustrates a clear version of this belief. Teachers with the

strongest beliefs reported they would almost always refrain from showing struggling students how to solve problems, and help such students rely, instead, on inner resources, such as informal knowledge. *Investigations* teachers, on the other hand, tended towards stronger beliefs that students can make sense of mathematics and that the understanding required for this sense making needs to be provided by teachers—especially for students who may be struggling. Understanding is cultivated from without, rather than within. Teachers from both programs emphasized sense making and connections as critical to learning.

Teachers' high point and/or turning point experiences, however, were closely linked to these conceptions about how to foster understanding in students. All eight teachers provided responses to the student strategy scenarios that reflected their stories of how they had increased their own understanding. *Investigations* teachers were more likely to focus on children's use of conceptually transparent strategies presented by the teacher, whereas CGI teachers tended to emphasize children's invention of strategies based on prior knowledge as ways to develop understanding. A few teachers, such as Ms. Ives and Ms. Carrera, expressed elements of both views. Teachers' responses to James's common invented strategy (described above and in the cases below) highlight these differences.

Finally, early negative experiences with mathematics appeared to exert a pervasive influence on teachers' current conceptions about the role of affect in understanding. The three teachers who reported consistently negative early experiences were more sensitive than the others to potential sources of confusion for students and expressed a stronger conviction in developing confidence in their students as a *prerequisite* to understanding. Other teachers were more likely to view students' explaining, and inventing as routes to mathematical understanding *and* confidence.

### Cases

In this section we present cases of one teacher from each program. The purpose is not to compare the two programs, but to examine how different combinations of knowledge and identity resources influence teachers' thinking about what it means to understand mathematics and how these differences may play out in their construction of reform-oriented practices.

#### Ms. Immendorf

Ms. Immendorf has taught for fewer than five years, and for all of those years has taught *Investigations*. She has participated regularly in district-sponsored workshops and credits her team at school as having the most positive influence on her perspective on mathematics. Although she had some strong negative experiences of failure in mathematics, she says now "I just love math. If I could teach it all day, I would."

Ms. Immendorf believes the teacher is a primary source of understanding for students. Her role is to provide students with alternative strategies, correct mistaken

strategies by showing other nonstandard strategies, and find out the origins of students' ideas. She does not, in general, encourage students to invent their own strategies, but if they do, she accepts it. Understanding develops primarily through awareness and use of multiple strategies and making connections, and to a lesser extent, following accepted conventions.

This set of conceptions about the nature of mathematical understanding appears to have been influenced by specific knowledge frameworks and identity experiences. For example, consider James (Table 1, item 3), the fictional student who used a developmentally predictable invented strategy to multiply two two-digit numbers. Ms. Immendorf noted that since James added 32 plus 32, he could have added that sum 12 times (i.e., use  $64 \times 12$  to figure  $32 \times 24$ ). But without this kind of obvious plan, she worried he was floundering. Next steps for him would include making multiple towers (e.g., 32, 64, 96, 128...) so he could skip count and look for patterns (e.g., counting by twos in the ones place). Instead of building on her insight about what James might have done, she opted for an approach she knew from *Investigations* as a precursor activity to multidigit multiplication. Her knowledge of the development of multiplication was founded on the conceptual organization presented in *Investigations*, rather than a framework for the progressive refinement of student-invented strategies.

Further, Ms. Immendorf brought to bear identity themes involving struggle in her speculation that James may not entirely understand his strategy: "but then the fact that he just keeps switching around and testing different things out without like a pattern, I would worry that maybe he's not quite sure what he's doing with it." This interpretation of the significance of James's strategy appears to rest on two formative ideas: that confidence is required to invent new strategies and children are easily confused. Ms. Immendorf expressed these ideas in her Identity Interview in several key events. She reported as a low point the time she "failed miserably" a college entrance exam for Algebra with no inkling beforehand she would not succeed. This blow to her confidence in herself and the system (she wondered why she had not been adequately prepared) took a great deal of effort to overcome. A high point for her was building the confidence of a boy who, at first, would cower under his desk rather than attempt a mathematics problem. But by the end of the year, "he would try different strategies. Like he wouldn't just take the paper and just totally throw it and get up under his desk."

### Ms. Cabrera

Ms. Cabrera has taught for about 20 years, and has spent the last three years in an upper-elementary bilingual classroom. She has been involved in CGI for six years and considers it the biggest "eye-opener" in terms of positive influences on her perspectives on mathematics.

Ms. Cabrera believes understanding originates in the self, and building identities as mathematically competent is a necessary component to understanding. The

teacher's role in building understanding is to highlight students' competence, set norms for the discussion of ideas, and encourage students to take risks. Mathematics consists of, among other things, "figuring things out on your own." Understanding is evidenced by inventing strategies, having reasons, making connections, and using multiple strategies.

As with Ms. Immendorf, these conceptions appear to be the result of a combination of knowledge and identity resources. Ms. Cabrera's hypothesized response to James's strategy was influenced in particular by her knowledge of a developmental progression of understanding multidigit multiplication and a strong belief in the validity of child-invented strategies. When presented with the strategy, she reported she had seen strategies like it many times, and noted it was more advanced than strategies involving pictures or base-ten materials. She wanted to question him about why he switched from chunking two 32s per group to chunking five 32s per group, and anticipated it would have something to do with being able to figure 20 32s more efficiently using chunks of 5. Rather than seeing confusion in James's actions, Ms. Cabrera saw an insight he may have had. She would discuss with students the kinds of connections they saw between James's strategy and other more and less sophisticated strategies.

Ms. Cabrera's strong belief in what her students know and can do was expressed in different forms throughout her Identity Interview. One of her earliest memories of mathematics involved a teacher who allowed her to win at the game of Bingo by pretending to choose her number. This act of caring made her feel like she was "successful" and "that somebody was there looking out for me." The theme framing this memory shows up repeatedly in Ms. Cabrera's thinking. With her involvement in CGI, she has also learned to see mathematics as an integral part of who her students are. Thus, knowledge of children's mathematical thinking has facilitated a new kind of caring for her students, for their mathematical identities.

When asked what her high point was, Ms. Cabrera said it involved helping students who do not see themselves as mathematical thinkers to see themselves in that light. She described an incident with such a student, Camila, who had used a strategy to solve  $\frac{3}{5}$  of 45 in way that "blew me away because I had never even thought of figuring a problem that way." Camila partitioned 45 into 15 groups of 3, and then took 2 from each 3, to get 30. She was having trouble verbalizing this strategy to the class, so Ms. Cabrera—who did not understand the strategy at first herself—questioned Camila until she understood it, and helped Camila explain it to the class. She wanted the class to hear this strategy because she wanted Camila to be successful and be viewed that way by her classmates. The context of this success, in contrast to the earlier experience winning Bingo, involved substantive mathematical thinking. The story frame is the same but the content is different, because knowledge Ms. Cabrera had gained allowed her to anticipate and appreciate children's invented strategies.

## Conclusion

All eight teachers in this study were experienced at teaching mathematics in ways that emphasized sense-making, connections, and communication. All felt positively about themselves as teachers and learners, even though uniformly positive identification with mathematics had not always been the case for them. All reported gaining knowledge as a result of implementing innovative mathematics approaches, and cited experiences illustrating the meaning this new knowledge held for their mathematical identities.

We found differences in the kind of knowledge teachers brought to bear to decide how to respond to fictional students, and in how teachers used their stories to interpret the significance of these potential pedagogical moves. Neither identity nor knowledge existed along a continuum that could be labeled “traditional” at one end, and “reformed” at the other. Instead teachers’ thinking placed differing emphases on what mathematics educators have argued are basic features of understanding: connections, application, generativity, justification, and identity (Carpenter & Lehrer, 1999; Lesh, Post, & Behr, 1987). However, in the absence of knowledge about the genesis of mathematical understanding in children, teachers tended to draw on identity resources to interpret the significance of unusual strategies; we will explore in future work the possibility that these differences are related to the kinds of opportunities to learn offered in each program.

Extrapolating from these findings, we propose that reflection on identity narratives may serve as a compelling change mechanism for teachers. It is natural to imagine alternative endings to stories or to retell a story with a different emphasis: stories “invite reconstrual of what might have happened” (Bruner, 1990, p. 53). One might ask Ms. Immendorf, for example, what would have happened had the system not failed her? How might the system have been different? This kind of reflection may help teachers distance themselves from their personal stories in ways that help them see other possibilities, and help them articulate salient influences on learning and identity. Equally important is teachers’ knowledge of mathematics and children’s thinking. Examining identity and knowledge in combination may result in an even more powerful framework for teacher change by identifying explicit relationships between the identity stories teachers tell and the knowledge that helps teachers act on and transform the critical elements of these stories. The way Ms. Cabrera facilitated Camila’s presentation of her unusual invented strategy illustrates the kind of mathematical empowerment that is possible under these circumstances.

## Note

<sup>1</sup>This research was supported by a Small Grant to the first two authors from the Spencer Foundation and by a research grant from the University of Texas at Austin. We thank the Spencer Foundation and UT for this support, the teachers and principals of

the two schools involved in this study for welcoming us into their classrooms, and Higinio Dominguez, Kevin Lopresto and Erin Turner for assistance in the research. The first author thanks the University of Wisconsin-Madison for support as a visiting scholar during the period of this research.

# **VEHICLE TO CONNECT THEORY, RESEARCH, AND PRACTICE: HOW TEACHER THINKING CHANGES IN DISTRICT-LEVEL LESSON STUDY IN JAPAN**

Aki Murata  
Northwestern University  
amurata@northwestern.edu

Akihiko Takahashi  
University of Illinois Urbana-Champaign  
takahash@uiuc.edu

Lesson study is the major form of professional development in Japan and has attracted attention in the United States in recent years. Lesson study currently conducted in Japan varies in terms of length, structure, and scale. District-level mathematics lesson study gathers teachers from different schools who share an interest in teaching the subject, and the discussion can focus more on particular aspects of teaching mathematics or content issues than that of in-school lesson study. The results of the survey indicate that lesson study provides opportunities for better communication among teachers, researchers, and administrators by presenting concrete classroom teaching examples surrounding particular educational ideas and/or issues, thus minimize the gap among theory, research, and practice. Implications to U.S. schools are discussed.

## **Purposes**

In this paper, we begin with describing what lesson study is and how various forms of lesson study differ from one another in their structures. We then report from our survey study how lesson study works to connect theory, research, and teaching practice in schools and how it can affect teacher thinking and learning to improve mathematics education in Japan. Lesson study is the major form of professional development in Japan, and some U.S. teachers have recently initiated it in their own schools (Germain-McCarthy, 2001; Research for Better Schools, 2000; Stepanek, 2001; Weeks, 2001). With the prospect of lesson study being incorporated in U.S. settings, it is important that U.S. practitioners be informed of the ways in which various forms of lesson study influence teacher thinking and practices in Japan so that we can better explore its potential impact on U.S. teachers. The idea of lesson study was introduced only around a small-scale and school-based study so far in the United States, and the effectiveness of lesson study has been discussed from data primarily based on observations. To date, no research has described how various forms of lesson study are organized and conducted in Japan, or what the experience means to Japanese teachers. It is our attempt to increase the international communication by reporting these aspects of lesson study, and thus, contribute to the collaborative effort to define a new model of lesson study in the United States.

## **Perspectives**

### **What Is Lesson Study?**

Lesson study is a form of professional development commonly and widely conducted in Japan (Fernandez, Chokshi, Cannon, & Yoshida, 2001; Lewis, 2000;

Lewis & Tsuchida, 1998; Shimahara, 1999; Stigler & Hiebert, 1999; Yoshida, 1999). In lesson study, teachers work collaboratively to: 1) formulate long-term goals for student learning and development, 2) plan, conduct, and observe a 'research lesson' designed to bring these long-term goals to life as well as to teach a particular academic content, 3) carefully observe student learning, engagement, and behavior during the lesson, and 4) discuss and revise the lesson and the approach to instruction based on these observations. The research lesson is taught in a regular classroom with students, and participants observe as the lesson unfolds in the actual teaching-learning context. Debriefing following the lesson is developed around the student learning data collected during the observation. Through the process, teachers are given opportunities to reflect on their teaching and student learning.

Lesson study embodies many features that researchers have noted effective in changing teacher practice, such as using concrete practical materials to focus on meaningful problems, taking explicit account of the contexts of teaching and the experiences of teachers, and providing on-site support within a collegial network. It also avoids many features noted as shortcomings of typical professional development; e.g., that is short-term, fragmented, and externally administered (Cuban, 1990; Firestone, 1996; Huberman & Gusky, 1994; Kennedy, 1999; Little, 1993; Miller & Lord, 1994; Pennel & Firestone, 1996). Furthermore, researchers have argued that lesson study is the critical system feature that has enabled Japanese elementary teachers to improve classroom instruction in mathematics and science in recent decades (Linn, Lewis, Tsuchida, & Songer, 2000; Lewis & Tsuchida, 1998; Takahashi, 2000; Stigler & Hiebert, 1999; Yoshida, 1999).

Lesson study has become visible in state, national, and international conferences, open houses, high-profile policy reports, and special journal issues in recent years in the United States. Moreover, some school districts in the United States have attempted to use it to change their practice and impact student learning (Coeyman, 2000; Council for Basic Education, 2000; Germain-McCarthy, 2001; Research for Better Schools, 2000; Stepanek, 2001; Weeks, 2001).

### **Different Types of Lesson Study**

The type of lesson study known and tried in the United States so far is small-scaled in-school lesson study. However, lesson study that is currently conducted in Japan varies in terms of length, structure, and scale. Besides the type of lesson study that is conducted within a single school, school districts organize lesson study for groups of teachers who share similar professional interests (e.g., subject matter) or who are at the same professional stage. Thus, district-level lesson study tends to focus on particular issues and topics to connect teachers from different schools. At other times, national-level research organizations conduct lesson study that gathers hundreds of teachers nation-wide.

At district- and national-level lesson study focused on mathematics, the teachers who participate are particularly interested in mathematics. They bring their knowledge of and experience with teaching mathematics to the study, and the level of the discussion is likely to be higher than that of the in-school lesson study. The main purpose of in-school lesson study can be to present opportunities for teachers whose main interest may or may not be mathematics to think about their teaching of the subject in general. At a district-level lesson study, the discussion can focus more on particular aspects of teaching mathematics or content issues. When it comes to national-level lesson study, the level of discussion may become very high. However, because of the large number of participants, they often cannot fit in a single classroom, and the research lesson presented may be considered unrealistic. For that reason, district-level lesson study maintains its unique middle-of-the-range characteristics.

Lesson study also plays an important role in improving curricula, textbooks, and teaching and learning materials in Japan. Most Japanese mathematics textbook publishers employ authors who are also classroom teachers involved in lesson study, and their materials are in some manner examined through the process of lesson study. The same situations can be found in the process of developing teaching and learning materials such as manipulatives and teachers' reference manuals. Japanese textbook publishers often include teachers' ideas and lesson plans that have been examined and discussed at district-level lesson study in particular because they are most likely to exhibit high mathematics content in a realistic manner.

District-level lesson study is often conducted to explore a new educational idea or a goal that is currently being explored, and a number of teachers across different schools come to participate for this type of lesson study. Each time the Course of Study was revised in Japan during the last few decades, lesson study across the country was conducted that particularly focused on exploring and demonstrating the new educational issues. Teachers collaboratively worked to illustrate how new ideas may be used in classrooms through their teaching, make the ambiguous aspects of the ideas come to surface, and set a stage for discussion for better understanding of the ideas in the future. The mechanisms of this type of lesson study will be discussed later.

### Methods

Survey questionnaires (Attachment) were sent to selected Japanese elementary school teachers who had played main roles in organizing district-level mathematics lesson study and are considered to be the leaders in the field. They lived in metropolitan Tokyo and its surrounding area and had thorough knowledge of how lesson study is conducted at the district-level. The total of 125 responses were collected.

For the 125 teachers, the median number of years they had taught was 16. They had participated in mathematics lesson study an average of 5 times a year, and taught research lessons in district-level lesson study an average of 10 times. They also reported that they thought approximately 35% of all Japanese teachers had taught a

mathematics research lesson at least once in their professional career, thus the average of 10 lessons taught indicated that the teachers who responded to the survey questionnaires were especially experienced in lesson study.

The questionnaires were designed to draw out information from the teachers regarding their experiences with district-level lesson study. They were specifically asked the (1) frequency and duration of district-level lesson study, (2) cooperative mechanisms between schools and districts in organizing a lesson study, (3) advantages district-level lesson study provides for teachers, and (4) problems or factors that should be improved for successful district-level lesson study. Multiple-choice/fill-the-blank questions were used to draw an overall picture, and open-ended questions then followed to gather details in teachers' own words.

After all the survey forms were collected, data were organized and compiled in a matrix to visualize the possible common categories. The data from multiple-choice questions were examined to draw a concrete image of the ways in which district-level lesson study is conducted in Japan. The data from open-ended questions were reviewed multiple times by two researchers to identify underlying threads that connected the responses from different teachers and different questions. The responses were then coded to indicate the teachers' beliefs, knowledge, and practice.

## **Results and Discussion**

### **How Is District-Level Lesson Study Organized and Conducted?**

Teachers responded that 98% of all school districts conduct mathematics lesson study regularly as a part of district-level professional development sessions. For the questions that asked the teachers to identify other activities likely to be included in those professional development sessions, 71% reported lectures by university professors and other authorities, 65% reported sessions for teachers to share each other's research, 40% reported model lessons taught by a known practitioner, and 28% reported workshops. The majority of the teachers (66%) reported that the professional development sessions in those districts were held approximately once or twice every trimester (Japanese school trimester range between 3 and 4 months).

Approximately half of the teachers (48%) responded that district-level professional development sessions are typically held in the afternoon of a regular school day. On those professional development days, schools in the district maintain the regular school day except for the school to be used for the lesson study. After all the students go home, teachers gather at the school where students remain for the extra class period for the research lesson. In other cases, the whole district cancels one school day and devotes it to professional development day (37%). Only the children in the classroom used for the research lesson attend schools for the lesson period.

In most cases, school districts or schools financially support district-level lesson study. Eighty-six percent (86%) of the teachers reported that districts cover the entire expenses (e.g., transportation), and 13% of the teachers reported they do so partially.

For lesson planning and teaching, 64% of the teachers reported that classroom teachers typically lead the district-level lesson study. It is a collaborative process, and 94% of the teachers said lessons are planned by a group of teachers together. They typically prepare lesson plans outside of their instructional time (84%), while on some occasions, schools make extra planning time within the regular school hours (4%) or the teachers do so on their own (6%). When a group of teachers work together to write a lesson plan and prepare for a lesson study, the teachers reported that they meet approximately 3 to 4 times (76%), more than 5 times (14%), or 1 to 2 times (10%) before the actual lesson study day.

### Teacher Changes

The teachers felt strongly that lesson study helped them improve their teaching. Almost all (98%) the teachers either agreed or strongly agreed that they had grown professionally by participating in lesson study and observing research lesson. Over ninety percent (91%) of the teachers also agreed or strongly agreed that lesson study is the most effective form of professional development. In comparing different forms of lesson study by ranking, 31% of the teachers reported that lesson study organized by an educational organization is the most effective, followed by district-level lesson study (26%), and lesson study held within a school (21%).

Many teachers described how seeing research lessons completely changed their beliefs about teaching. They described the experiences in their own words (translated from Japanese) as follows:

When I was young, I used to have the attitude that teachers needed to teach everything, but through lesson study, I came to think that teachers are the learning “assistants” for students and it is important to carefully prepare lessons so that students can investigate and solve problems on their own. (Number of years taught 9, average number of times participated in lesson study per year, 3)

I used to think the lessons that are aligned closely to textbooks are the best ones for students. After seeing research lessons where teachers tried to make a textbook lesson closer to students, I started to think about and search for good teaching material for my students as I plan mathematics lessons. (Number of years taught 12, average number of times participated in lesson study per year 2)

When I was young, I thought teaching was to make a point and explain students so that they can understand better. So, to me, back then, it was critical to find the ‘technique’ to do that effectively. After seeing the investigative open-ended lesson, I have come to think that learning is not what I had thought. (Number of years taught 17, average number of times participated in lesson study per year, 6)

Another teacher noted about his experiences as follows:

I don't see my teaching as a complete "instructional method" any longer. I now see the methods that may possibly become a part of good instruction. (Number of years taught 13, average number of times participated in lesson study per year 12)

Lesson study helps Japanese teachers experience good teaching practice when the ideas may not appeal to them theoretically. Seeing the successful examples helps teachers understand the benefit of the different and/or unfamiliar practices, and they come to see the good lesson in terms of children's learning across different theories and approaches.

### **Connecting Theory and Practice**

The teachers indicated that they saw lesson study as an important and effective link between educational theories and their classroom practice. Many teachers responded that seeing new ideas demonstrated in research lessons and participating in discussion of the actual practice strengthened their understanding of such ideas. They described the experiences as follows:

(To US teachers,) I think it is important to actually teach lessons and get feedback from others, and not just reading theories in books or attending lectures. (Number of years taught 1, average number of times participated in lesson study per year 1)

It is hard to incorporate new instructional ideas and materials in classrooms unless we see how they actually look. In lesson study, we see what goes on in the lesson more objectively, and that helps us understand the important ideas without being overly concerned about other issues in own classrooms. (Number of years taught 22, average number of times participated in lesson study per year 20)

On more practical side, many teachers reported that seeing actual materials used in the research lesson classroom helped them understand the benefit of the materials in the particular lesson to help children's learning.

For teaching the unit on large numbers for second grade, I saw how one-yen coins (pennies) were used effectively, and the small trays that accompanied the activity. (Number of years taught 1, average number of times participated in lesson study per year 1)

When I see an effective use of manipulatives, a bulletin board, or a good way the teacher presents an investigative situation using questions, I take the idea to my classroom and use it. (Number of years taught 10, average number of times participated in lesson study per year 5)

I learned what to prepare for the open-ended investigative problem solving (hint card, etc.). (Number of years taught 11, average number of times participated in lesson study per year 4)

Lesson study provides live examples for teachers to see and experience how educational ideas are played out in actual classrooms. Seeing the actual practice makes it easier for the teachers to think and adapt the ideas. Even for novice teachers, they reported that participating in discussions with more experienced peers using concrete classroom data helped them understand the importance of the new ideas and apply them practically. Lesson study plays a critical role in connecting theory and practice in Japanese education, and may potentially do the same for U.S. schools.

### **Implication and Conclusion**

With the absence of national curriculum and shared vision, U.S. teachers are sometimes left alone to make everyday teaching decisions in their own classrooms. When the larger culture values autonomy and independence, it makes it even harder for them to communicate with one another. This not only makes their work more difficult but also keeps them from learning from one another to improve the learning chances of their students. Well-crafted educational theories may be understood partially and taken by pieces by different teachers and lose their original shape when communication is limited. The Japanese teachers who responded to the survey indicated that this is not a unique situation in the United States, however, and Japanese teachers also struggle to make sense of new ideas and help them come to life in their classrooms. Lesson study provides opportunities for better communication among teachers, researchers, and administrators in Japan by presenting concrete classroom teaching examples surrounding particular educational ideas and/or issues. Discussions focused on the particular classroom examples or data helps people to communicate better and understand one another. Lesson study will potentially help create a place and a reason for all people who work to improve education of our children to gather and discuss their ideas within the actual U.S. classrooms. The commonly seen disconnect between theory, research, and practice may be minimized just by having such a common place for all.

As we continue our collaborative effort to define U.S. lesson study model, future studies should explore the effect of lesson study on teachers and students by going beyond their self-reports and observations. The studies are needed that address the particular aspects of teacher learning and teacher change as a result of their participation in lesson study, and the influence of such changes on students learning in the classroom. Focused case study of a particular teacher, video-tape analysis of the changes in teaching practice, and/or careful examination of students' understanding of mathematics before and after the teacher participates in lesson study may provide us different pictures of its potential effectiveness in U.S. mathematics classrooms.

**Questions about mathematics lesson study**

1. At your district, is mathematics lesson study conducted regularly? Yes / No
2. For the following questions, please take your overall experience with lesson study in consideration (not only of your current school district)
  - (a) In general, how often do you think district-level mathematics professional development sessions are held? Once a month / Once or twice a trimester / Once or twice a year / Other
  - (b) In general, how often do you think lesson study is conducted as a part of the district-level mathematics professional development? Once a month / Once or twice a trimester / Once or twice a year / Other
  - (c) What other activities do you think are part of the district-level mathematics study session? (Please choose as many as you wish) A lecture by a university professor / A model lesson taught by a known practitioner / A session for teachers to share each other's research / Workshops / Other
  - (d) How do you think teachers make time to attend district-level mathematics lesson study? The whole district cancels a school day and keeps only the children in the classroom used for the lesson study / The whole district uses the after-school hours and keeps only the children in the classroom that is to be used for the lesson study / The whole district conducts lesson study during the regular school time and teachers assign independent work for students during their absence / Other
  - (e) Who is financially responsible for teachers' expenses to attend district-level mathematics lesson study? (e.g., transportation) School district or school covers the whole expense / School district or school covers the partial expenses / Participating teachers pay on their own / Other
  - (f) In general, who leads the district-level mathematics lesson study? School district or instructional department of the district / School administrators / Classroom teacher who belongs to the research committee / University professor or researcher (external) / Other
  - (g) In general, who makes the lesson plan for a district-level mathematics lesson study? School district or instructional department of the district / University professor or researcher (external) / The teacher who teaches the lesson / A group of teachers including the teacher who teaches the lesson / A group of teachers not including the teacher who teaches the lesson / Other
  - (h) How do teachers make time to prepare for the district-level mathematics lesson study? (e.g., writing a lesson plan) For the teacher who teaches the lesson or the others who help the lesson planning, schools make extra planning time for them within the regular school hours / The teachers make time within their instructional time on their own / The teachers plan outside of their instructional time / Other

## COURSE CONCEPTUALIZING THAT AIMS TO PSYCHOLOGIZE THE CURRICULUM IN CALCULUS

Dara Sandow  
Michigan State University  
sandowda@msu.edu

A century after Dewey wrote *The Child and the Curriculum*, we still have an inadequate understanding of what it takes to psychologize the study of mathematics. In this report, I present a case study of an Advanced Placement Calculus teacher who aims to psychologize the study of calculus for his students. I highlight the role of course conceptualizing—reasoning about and choosing among course-level alternatives—in his efforts, focusing on choices he makes in three categories of alternatives: describing what calculus is about, organizing the substantive content of the course to support students' learning, and representing knowing in mathematics. The teacher's strategic choices in each of these categories support his efforts to psychologize calculus. Using this case as an illustration, I argue that conceptualizing as a course-level practice can play an important role in psychologizing the curriculum.

In *The Child and the Curriculum*, Dewey (1902/1990) argues that we must move beyond an artificial polarization between child-centered and subject-centered instruction. Rather, he calls for *psychologizing the curriculum*: learning to see important elements of the subject matter in students' current understandings and interests and figuring out how to use the latter to support students' learning. Dewey claims that we must get rid of the prejudicial notion that there is some gap in kind (as distinct from degree) between the child's experience and the various forms of subject-matter that make up the course of study. From the side of the child, it is a question of seeing how his experience already contains within itself elements—facts and truths—of just the same sort as those entering into the formal study; and what is of more importance, of how it contains within itself the attitudes, the motives, and the interests which have operated in developing and organizing the subject-matter to the place which it now occupies. From the side of the studies, it is a question of interpreting them as outgrowths of forces operating in the child's life, and of discovering the steps that intervene between the child's present experience and their richer maturity. ... Just as two points define a straight line, so the present standpoint of the child and the facts and truths of studies define instruction. It is continuous reconstruction. (p. 189)

He claims that not only is it possible to see a continuity between students and subject matter, but essential, for it is the interaction between the two that lies at the heart of effective education. Moreover, this need not be a forced interaction. Rather, because studies are a human creation, they can be connected to the interests and experiences of all humans. The teacher is responsible for facilitating this interaction:

What concerns him, as teacher, is the ways in which that subject may become a part of experience; what there is in the child's present that is usable with reference to it;

how such elements are to be used; how his own knowledge of the subject matter may assist in interpreting the child's needs and doings, and determine the medium in which the child should be placed in order that his growth may be properly directed. (p. 201)

Dewey goes on to discuss three "evils" that result when "the material is not translated into life-terms, but is directly offered as a substitute for, or an external annex to, the child's present life" (p. 202): the purpose for which symbols are initially created—the attempt on someone's part to symbolize an idea that has genuine meaning for that person—is lost and the symbols become purely formal; the felt need and therefore much of the motivation for ideas is lost; and the organizing function of the discipline—the extent to which the disciplinary structure facilitates sense-making and problem-solving that would otherwise be difficult—is no longer apparent. These concerns are particularly relevant in mathematics, given the importance of symbols and logical foundations within the discipline. Dewey points out that because teachers must always deal with the psychological, when they use a logical approach, they often end up motivating students in inauthentic ways, e.g., by habituating them to routine, penalizing them for poor work, or sugar-coating the material with fun activities.

I value Dewey's insights in identifying the construct of psychologizing the curriculum, highlighting its importance, and elaborating its meaning. Still, having a goal of psychologizing the curriculum doesn't tell one how to go about it. Few detailed images exist of teachers' explicit attempts to psychologize the curriculum, especially in secondary mathematics (see Chazan, 2000, however, for an example). Moreover, as soon as one turns to practice, questions arise about the basis on which one claims that the curriculum has been psychologized. Dewey's discussion focuses on the teacher, e.g., the need for a teacher to interpret students' experience with respect to the subject's "facts and truths" and "the attitudes, the motives, and the interests" central in its development. The role of students is more ambiguous. Students' experiences, attitudes, and interests are clearly central to psychologizing; however, it is unclear whether students must experience efforts to psychologize the curriculum as motivating for such efforts to be seen as effective, especially for students already used to routine, grades as external motivators, or sugar-coating. In addition, Dewey writes about the child (singular), whereas teachers are faced with trying to psychologize the curriculum with a class of students whose experiences, attitudes, and interests often differ in significant ways. And while day-to-day teaching is central to psychologizing because each student's "present" continually shifts, curriculum is more than a collection of individual lessons, and therefore one must also find ways to look across a course.

In this paper, I will focus on the teacher's efforts at the course level, in particular, the role of a practice I call *course conceptualizing*: reasoning about and deciding among alternatives that play out at the course level. I will use examples from a case study of an Advanced Placement calculus teacher, Marty Schnepf,<sup>1</sup> to illustrate a relationship between course conceptualizing and psychologizing, arguing that a desire to

psychologize the study of calculus is a central consideration in Marty's reasoning as he chooses among or invents alternatives while conceptualizing and that course conceptualizing can play an important role in efforts to psychologize the curriculum.

### Course Conceptualizing as a Construct

Course conceptualizing is a practice of some teachers. It involves reasoning about course-level aspects of a course (e.g., what the course is about, how to organize the course content to support students' learning) rather than unit- or lesson-level aspects, with a recognition that alternatives exist. I restrict my use of this construct to courses intended to have some unity of content, whether by branch of mathematics (e.g., calculus, algebra) or theme (e.g., modeling). Course conceptualizing draws on—and can contribute to the development of—a person's *landscape of alternatives* for a given course: the alternatives that person knows about and the ways in which he or she has made sense of them. Different people's landscapes of alternatives may vary in how they categorize alternatives and think about those categories, which alternatives they know of within a given category, and the level of detail in which a given alternative is known. For example, many people think about the organization of content in terms of sequencing, but Lampert (2001) prefers to think about this in terms of a terrain. Some people know of alternative sequences for a given course, but the alternatives known by one person may be different from those known by another, and a given person might know of one sequence in detail and others more sketchily. Chazan (1999) identifies another category of alternatives, a course's "approach": the fundamental objects of study for the course, the questions one asks about them, and the other important objects of study that arise in the context of the fundamental objects and questions. But, others think about the content of a course in other ways (e.g., scope).

Teachers engage in course conceptualizing for a variety of reasons, for example, to make sense of new curricular materials, to better understand the differences between two alternatives, to figure out an alternative to something unsatisfying at the course level. Although alternatives often come from outside sources (e.g., curricular materials, talking to colleagues), course conceptualizing can involve inventing an alternative of one's own. A common goal of conceptualizing is to develop a *course conceptualization*: a particular constellation of alternatives chosen from the categories one has considered. An important conceptualization is the way in which one has made sense of a course in light of materials one must use; this might or might not be the conceptualization one prefers for that course.

### Methods

This investigation is part of a pilot study. I am designing a more comprehensive study of teachers' course conceptualizing and conceptualizations to better elaborate these constructs. My methodology is qualitative. The data consist of two hour-long interviews with Marty about his calculus course, focused on his goals for his students,

how he structured the course, and what he valued about these goals and structure; videotapes from a single section of his calculus course, taped daily for one year; audiotapes of presentations Marty made to mathematicians and mathematics educators about his calculus teaching; and copies of Marty's published and unpublished writing. I first searched through the interview transcripts, presentation transcripts, and writing for discussions of choices Marty made about the course and analyzed these to produce a description and interpretation of his calculus course conceptualizing and preferred conceptualization (Sandow, 2002), using my yearlong classroom observation and sample videotapes from different points in the year to better understand Marty's descriptions of his goals and considerations. This analysis was oriented around scope and sequence (Tyler, 1949) and ontological and epistemological content, broadly interpreted (e.g., fundamental objects of study, Chazan, 1999; knowing in mathematics, Lampert, 1990; substantive and syntactic structures, Schwab, 1978), with attention to Marty's ways of considering these (Strauss & Corbin, 1990). I then analyzed Marty's conceptualizing and preferred conceptualization to identify choices that represented efforts to psychologize the curriculum for his students.

### **Marty's Calculus Course Conceptualizing**

#### **An Introduction to Marty**

Marty has been teaching for 14 years altogether, 11 of them teaching calculus. For the last 11 years, he has taught at Holt High School (HHS), a Professional Development School (PDS) associated with Michigan State University (MSU). A number of experiences have contributed to Marty's efforts to redesign his calculus course. He has worked as a teacher-researcher for the last five years with the SimCalc project at TERC, piloting the use of "line becomes motion" technology, in which distance-, velocity- and acceleration-versus-time functions can be entered into a computer graphically or symbolically and used to drive the motion of one of two devices connected to the computer: a small wire bicyclist named Eddie who pedals in place and two toy mini-cars that move along parallel straight tracks (Schnepf & Nemirovsky, 2001). Two courses he took while completing his Master of Arts in Curriculum and Teaching at MSU were also particularly influential, one on philosophies of mathematics and their connections to teaching, with Bill Rosenthal, the other on post-modern philosophies of education, with Cleo Cherryholmes. In addition, a broader PDS initiative at HHS supported released time for teachers to co-teach (Chazan, Ben-Chaim, Gormas, Schnepf, Lehman, Bethell, et al., 1998) and contributed to a restructuring of the teachers' workweek to give them a three-hour block of time on Wednesday mornings in which the teachers could work collaboratively or independently on projects or other work supporting their professional development. (Chazan, Lehman, & Bethell, 2002, describes the HHS mathematics department's PDS work and its impact in more detail.) The PDS initiative also created significant opportunities for MSU mathematics edu-

cation faculty and graduate students to work with members of the HHS mathematics department and carry out research in this context (see, e.g., Chazan, 2000). It was as a PDS research assistant that I first came to know Marty and his calculus teaching.

### **Developing a Course Conceptualization Aimed at Psychologizing Calculus**

Although at the time of this study Marty hadn't read *The Child and the Curriculum*, he talks about his goals in ways that are quite consistent with Dewey's argument. He writes, "I want to hear what my students think, in some detail, and then figure out how to connect what they think to what others have developed" (Chazan & Schnepf, 2002, p. 187). In this section, I present three examples of ways in which Marty's desire to psychologize calculus for his students influences and is supported by his course conceptualizing: describing what calculus is all about, organizing the substantive content to support student learning, and representing knowing in mathematics.

#### **Describing What Calculus Is All About: Choosing the Fundamental Objects of Study for the Course**

Marty writes that he wants his students "to appreciate that Calculus is about something" (Chazan & Schnepf, 2002, p. 179). He identifies that "something" as rate, accumulation, and the relationship between them:

We started out in the fall with looking at examples of something that the kids would have some kind of experience with, where something was changing at a varying rate. And just trying to figure out how much of it had accumulated, 'cause ... they've got lots of experience computing rates and watching rates. ... They're presented with a new idea: what if the rate changes over the course of the time? And that naturally raises questions for them about what a rate is, and whether or not you need a time interval for a rate. And they've been pretty loosely using the term "average rate," and [we explored] what that really means. So we sorted all of that out, and we went into looking at problems where you vary a quantity and you want to know about its rate instead, so going the other direction. ... Then we started looking at the relationship between going back and forth on those. (interview)

Choosing to describe calculus as about rate, accumulation, and the relationship between them makes it possible for Marty to present his students with situations "that the kids would have some kind of experience with" and in which central ideas of calculus are embedded, making it possible for the students to develop solution methods and talk about them before they've been introduced to the formal vocabulary and methods, thereby motivating the latter. To help guarantee that the situations are truly ones that all of the students have experience with, Marty brings physically immediate experiences into the classroom: on the first day of class, he pedals his own bicycle at a varying rate on a stationary trainer in front of the students, and later the class uses

the moving TERC devices [(i.e., Eddie and the mini-cars). Although in the quote above, Marty doesn't explicitly contrast his framing of what calculus is all about with alternative choices, he distinguishes between rate/accumulation and differentiation/integration (e.g., "When students discuss integration, we want them to recognize (1) that accumulation always occurs *at a certain rate* and (2) that this rate at any given point *is* the value of the function being integrated," (Schnepf & Nemirovsky, 2001, p. 91)], implying that he sees these as different objects of study.

Marty's choice is relevant to psychologizing in a second way, for as Dewey notes, "the problem of the relation of the child and the curriculum presents itself in this guise: Of what use, educationally speaking, is it to be able to see the end [the subject-matter of the studies] in the beginning [the child's present experience]?" (p. 190). Therefore, teachers must articulate for themselves what the end *is*, which again raises a question of what calculus is all about. Marty identifies a deep understanding of the Fundamental Theorem of Calculus as an important element:

Although students usually intuitively see adding and subtracting as "undoing" one another, most calculus students do not develop an equivalent sense of why integration "undoes" differentiation and vice versa. ... We want to build the core of calculus education, from day one to the final test, around the development of this insight. (Schnepf & Nemirovsky, 2001, p. 91)

Dewey (1902/1990) goes on to say that this problem is partly one of seeing how a child's "crude beginnings .... may get clarity and gain force" (p. 195), for clarity and force help define studies in that they characterize the elements of studies that make "the net product of past experience ... most available for the future" (p. 199). Some aspects of studies—often referred to as "the big ideas"—clearly provide more insight and power than others. In calculus, the Fundamental Theorem is one of these (hence its name and its role in Leibniz and Newton getting credit for inventing calculus). Thus, although Dewey initially writes about connecting the child's present to the "the facts and truths of studies" as if the facts and truths were all equally worth knowing, studies' big ideas play a special role in psychologizing.

### **Organizing the substantive content to support student learning.**

Describing calculus in terms of rate, accumulation, and their relationship also allows Marty to shift the sequencing of the topics in the course relative to the traditional sequence. Among other things, it allows him to postpone a formal treatment of limits until much later in the course. He notes that starting with limits is problematic because the students are not yet in a position to understand why the limit concept, much less a rigorous limit definition, is needed:

When I tried starting with limits in calculus, for example, it was completely disconnected for the kids, so that was a drawback. Um, they didn't understand why anybody would be concerned with anything like that. I thought

that was a pretty legitimate question, so as I started looking back in the history of calculus that, you know, limits evolved out of arguing about how you talk about rate of change at an instant .... And so it seemed to make a lot of sense to me to help make sure the kids understand what kind of problems were being tackled historically that lead them to conversations about limits or ... why different conventions have evolved and just why a given topic exists. (interview)

Instead of starting with limits, the class initially works only with polynomial functions and develops a theory of differentiation and integration for those, using their intuitive understanding of limiting processes. Later in the year, when they work on generalizing their theory to other kinds of functions, more precise notions of limits and continuity are needed and then get developed. Thus, Marty recognizes that there are alternative ways of organizing the course content, and he chooses to organize it such that his treatment of limits is consistent with Dewey's injunction against presenting material as "an external annex to the child's present life" (p. 202) and the concomitant "evil" of losing the felt need and motivation for a concept. Moreover, he recognizes that as they move to more abstract work, there's a risk that students will lose sight of the abstractions ever having been connected to their own experiences. To help the students maintain a connection, the class returns to the moving TERC devices later in the year, reinterpreting the formal theory in terms of their motion.

Marty recognizes that the question of whether particular content is external to students' lives must always be judged in relation to his actual students and the ideas they introduce and are intrigued by. Therefore, although he has a characteristic way of organizing the course content, which he describes in terms of "having a coherent storyline for [the course]" (interview), the organization sometimes plays out differently in different sections, depending on the ideas that students introduce and find intriguing. Marty notes:

The other major influence on how the course is sequenced is sort of what they choose, or what the students tend to do with the material; you know, that will change different topics, sequences and things, depending on how they start talking about it. You know, if the two-sided [limit] issue had become relevant earlier, back in the fall, we could have done limits then. (interview)

In fact, this happens the following year:

This year, they got to that point [of working with limits informally], and they just wouldn't let go of it. Um, they didn't know what limit really meant, and so we actually did look at ... limits more formally, where typically that's come second semester. (presentation)

In addition, consistent with Marty's desire to motivate the relationship between integration and differentiation, he pairs several topics in unusual ways: the chain rule

for derivatives with u-substitution (representing composition), the product rule and integration by parts (representing products), and implicit differentiation, related rates, and separable differential equations (representing implicit or parameterized relationships).

### **Representing Knowing in Mathematics: The Nature of Mathematics and Its Practice**

In addition to wanting his students to learn about the substantive content of calculus, Marty wants his students to develop certain beliefs about the nature and practice of mathematics, including beliefs about themselves in relation to mathematics. These additional goals are relevant to psychologizing the curriculum, for as Dewey (1902/1990) points out, an important aspect of psychologizing is recognizing how the child's experience "contains within itself the attitudes, the motives, and the interests which have operated in developing and organizing the subject-matter to the place which it now occupies, ... [for this aides in] discovering the steps that intervene between the child's present experience and their [the studies'] richer maturity" (p. 189). These goals are also a part of Marty's course conceptualizing, both in the sense that he recognizes this as an explicit part of the content of his course (even though this is not usually articulated as part of course content) and that other teachers portray a different image of mathematics to their students.

For Marty, one theme of knowing in mathematics is wanting his students to see mathematics as a way of describing the world that then takes on a life of its own, a life in which internal consistency is essential. Because consistency can be difficult to determine oneself, social interaction, especially the comparing of different people's interpretations and understandings of a particular idea, is also an important part of mathematics:

[I want my students to understand that] people have developed this symbolic system for describing what they seen in the world around them, ... for describing quantities and shape around them. ... And so I want kids to, first of all, think about it as these are just descriptions for things that occur, but then once you create the descriptions, you need to look for internal consistencies and for the conclusions that you can draw using that system as a tool. ... It's checks for consistency, but those checks need to go on from person to person to clarify thinking. ...

What I want kids to think about what mathematics is: ... it's looking at a situation and creating some way of describing it or techniques for dealing with it, and then once you've created those things, let them take on their own life and see what they look like and see how they relate to all the other stuff that you know. (interview)

Consistent with Dewey's exhortation not to address the psychological by sugar-coating the content (i.e., "get[ting] the child to swallow and digest the unpalatable morsel while he is enjoying tasting something quite different," p. 208), Marty says that he doesn't introduce mathematics as describing the world in order to present "real-world applications" or to make the course more fun:

I don't know if I'd call it a plausibility thing, like it's plausible that someone would actually be interested in doing this or it would be useful to do it. That's where it targets some kids, but mostly ... I want to come up with some kind of problem that has the mathematics we need to study embedded in it, in some way that has some kind of intuitive appeal. I certainly do everything I can to avoid "oh, I do it to make it interesting or make it fun." Because a lot of this stuff may not be interesting or fun, ... and there's no way that you could ever do that for every kid in your room. (interview)

Characterizing mathematics in the manner described above supports psychologizing in several ways. First, it creates an atmosphere in which actual and hypothetical physical experiences are seen as relevant. Students can then use the ideas of accumulation and rate to describe these, helping them make connections between their experiences and the mathematics they are studying. Second, students' differing ideas and interpretations become valuable. And third, it creates a way to arrive at the "richer maturity" of mathematics without starting there. Marty has found that prematurely formalizing language and notation shuts down students' exploration. Instead, as the students themselves introduce ideas about rate and accumulation, he and the students gradually develop language and symbols to capture those ideas. He writes that "frequent classroom discussions focus on revising the meanings of familiar words—speed, velocity, average, distance, and so on—and constructing mathematics related to their technical use" (Schnepp & Nemirovsky, p. 101). For example, a student recognizes that they are using "average rate" in different ways and that they need a definition; Marty has them propose definitions and work on this, revisiting it over time as they make sense of the difference between averaging a discrete set of values and averaging something that varies continuously.

A second theme is that Marty wants his students to develop a sense of their own mathematical authority. The authority of textbooks and teachers poses a significant obstacle to this, especially since his students may have already become habituated to being told "the answer." Thus, Marty intervenes in a dramatic way in his talk and his textbook use. Believing that his students need time to learn to persist and develop greater intellectual independence, he essentially refuses to tell them whether they are right or wrong for the first two months or so of the course:

In my view, the danger of responding, "yes what you are doing is correct," or "no what you are doing is wrong because ...," is perpetuating students'

reluctance to make sense of and analyze arguments for themselves. If I pass judgment on ideas and methods—to prevent students from pursuing a dead end approach for example—students will learn to look to me to assess validity of arguments and not learn to do such reasoning independently. (Chazan & Schnepp, 2002, p. 174)

To get the kind of sense-making I want, there has to be an extended period of time where kids can ... go through their emotional stage of being mad at me because I'm not telling them the answer, [so] they can finally figure out "OK, wow, I *can* make sense of this." (presentation)

In addition, Marty doesn't use a textbook during the first semester, maintaining that his students can only make truly productive use of textbooks once they understand what motivated the development of the ideas in the text and feel that they can critique the text's representation instead of relating to the text with a sole goal of mastering content:

The textbook tends to be full of stuff that the kids haven't thought about yet, and if it's used as the sole basis for the class, [students are] constantly being thrown into situations where they don't really understand what lead to the kind of stuff the person's going to talk about .... It gets in the way in the sense that it's such a finished polished product in terms of the, the mathematical structure and the presentation of it. ... A high school kid looks at that and says "OK, my job is to try to understand the stuff that, you know, is truth" ..., and it's just such a completely different mind set than what I think I would want people doing. I mean they're not going to think as critically about it if they're not critiquing it or if they don't know exactly what went into creating that. ... There's just something so different about the process, I think, when you're critiquing something versus when you're just trying to understand what it's saying. (interview)

Marty's hope is that by the time they move to the book, the mathematical objects and writing are themselves psychologized to a greater degree, and therefore that using a text is not as disconnected from psychologizing as it might be. Not using a textbook also makes it easier for Marty to move around in the material flexibly in response to ideas that the students introduce.

### **Revisiting the Construct of Course Conceptualizing**

Before discussing the relevance of course conceptualizing to psychologizing, I briefly return to the constructs I introduced above, using this case to illustrate them. Marty has engaged in course conceptualizing in calculus—reasoning about course-level issues with a recognition that alternatives exist—in order to develop a course conceptualization that psychologizes calculus for his students. In his landscape of

alternatives, the categories include describing what calculus is about, organizing the substantive content of the course, and representing knowing in mathematics. He makes explicit some of the alternatives that he knows about within a category [(e.g., in the category “organizing the substantive content of the course,” he explicitly rejects a common alternative: starting with a treatment of limits; and elsewhere, he writes that with differentiation and integration, “rather than studying one and then the other, students encounter and then reencounter both at once (or in succession) in different contexts, levels of analysis, and representations,” (Schnepp & Nemirovsky, 2001, p. 93), contrasting another of his choices with an alternative]. Although he may not explore all of the alternatives he knows about in depth, he recognizes that alternatives exist and that there are choices to be made or invented. He is articulate about his reasons for choosing certain alternatives, and these come together to form his preferred course conceptualization for calculus. This conceptualization is not a simple union of the chosen alternatives; rather, it is a complex coordination in which choices from different categories interact with and often support each other.

### **The Relevance of Course Conceptualizing to Psychologizing**

Much of the work of teaching obviously occurs in day-to-day planning and classroom interactions. And because students’ “present,” which is always changing, plays such a central role in psychologizing, the day-to-day work of teaching is especially important in efforts to psychologize the curriculum (e.g., in assessing students’ current understandings, interests, etc., and using that understanding together with an understanding of the discipline to figure out where to go next). Nonetheless, conceptualizing as a course-level practice has much to contribute to efforts to psychologize the curriculum.

First, when working with students for whom mathematical objects are not yet psychologized, one must look for alternatives to the (mathematically) logical progression (e.g., in calculus, limits are unlikely to be an appropriate place to start the course). Moreover, even if one has a preferred sequence and believes it connects to students’ experiences in valuable ways, one must still think about the content in ways that allow one to be responsive to students’ thinking along the way; thus, organization might be better thought of as a terrain (Lampert, 2001) in which one chooses the starting point ahead of time and in which the next step is determined jointly by the ideas that students introduce and the one’s knowledge of the overall set of understandings one wants students to develop. A second, related, point is the value of looking for a way of framing the substantive content of the course such that the course is about something that can be communicated to students before they’ve been introduced to formal vocabulary and allows them to engage with problems before they’ve been introduced to formal solution methods.<sup>2</sup> The big ideas of the discipline likely play an important role in deciding what a course is about. Nonetheless, the fundamental objects of study need not be mathematical objects; rather, they may be objects like rate and accumula-

tion, for which meanings exist in both natural language and the mathematics register. Third, psychologizing the curriculum necessitates attending to the nature and practice of mathematics, and thus to making explicit for oneself the attitudes, motives, and interests that have “operated in developing and organizing the subject matter.” Not only would attempting to psychologize the substantive content alone be incomplete in Dewey’s eyes, it may actually be difficult to psychologize the substantive content without attending to the attitudes, etc. that lead to its development. Finally, the practice of course conceptualizing—especially the act of considering alternatives (which can involve such things as naming alternatives and seeing both distinctions and connections among different elements)—may set teachers up to listen to their students more flexibly, which puts them in a better position to psychologize on the day-to-day level. In light of its role in psychologizing the curriculum (as well as its potential role in helping teachers understand diverse approaches in this era of curriculum reform), course conceptualizing deserves our attention.

### Notes

<sup>1</sup>I use the teacher’s actual name with his permission.

<sup>2</sup>Chazan (1999, 2000) reasons similarly in arguing for a functions-based approach to school algebra.

# **PRESERVICE ELEMENTARY AND MIDDLE SCHOOL TEACHERS' CONCEPTIONS OF ALGEBRA REVEALED THROUGH THE USE OF EXEMPLARY CURRICULUM MATERIALS**

Sheryl Stump  
Ball State University  
sstump@bsu.edu

Joyce Bishop  
Eastern Illinois University  
cfjdb1@eiu.edu

One of the greatest challenges for mathematics teacher educators committed to reforming and improving mathematics education is to help preservice elementary and middle school teachers develop an appreciation for algebraic reasoning. Preservice teachers' views of algebra are typically derived from their experiences in middle school and high school where they developed a conception of algebra as a body of rules and procedures for manipulating symbols. However, as Moses (1997) observed, the content of algebra is being transformed from a discipline involving the manipulation of symbols to a way of seeing and expressing relationships, "a way of generalizing the kinds of patterns that are part of everyday activities" (p. 246). In elementary and middle school, the crucial issue now appears to be the development of algebraic reasoning, with a focus on relationships, not just the introduction of algebraic concepts (Yackel, 1997). An important goal for mathematics teacher educators is to organize experiences for preservice teachers that will broaden their vision of algebra so that they can effectively promote the algebraic reasoning of elementary and middle school children.

This investigation focused on an algebra course for preservice elementary and middle school teachers who have chosen mathematics as their area of specialization. The goals of the course are (1) to develop preservice teachers' understanding of algebraic concepts, (2) to encourage preservice teachers to focus on children's algebraic reasoning, and (3) to foster more conceptual views about the nature of algebra. The research mission of this investigation was to assess progress toward meeting the goals of the course.

Recommendations from various professional organizations (CBMS, 2001; MAA, 1991; NCTM, 1991) have outlined the algebraic content appropriate for preservice teachers. This content includes investigating patterns, representing problem situations with variables, analyzing functional relationships, and investigating algebraic structure. Although it may be difficult to address all of these topics meaningfully in a one-semester course, we decided to use this collection of topics as the framework for the content of our course (Stump & Bishop, 2001). As we address these topics, we wish to shift the emphasis away from symbolic manipulations and toward a broader and more relationship-oriented view of algebra.

Bednarz, Kieran, and Lee (1996) suggested four conceptual approaches for developing algebraic ideas with children – generalization, problem solving, modeling, and

functions – and these four approaches also offer promising alternatives for developing algebraic ideas with preservice teachers. As described by Bednarz, Kieran, and Lee, *generalization* focuses on the construction of formulas that account for general procedures or relationships among quantities. *Problem-solving* emphasizes the forming and solving of equations, using letters as unknowns. *Modeling* involves algebraic representations arising out of real-world situations, and relationships originating in observations or measurements. A *function* approach examines various representations of dependence relationships among real-world quantities, observing how change in one variable produces variation in another variable. Each of these approaches provides a different setting in which the focus is on the development of conceptual knowledge and algebraic reasoning. For our purposes, we have collapsed these four approaches into three: generalization, problem solving, and a combination of functions and modeling. In our view, modeling a physical situation frequently involves identifying the function that explains the situation, and the emphasis on relationships that is inherent in work with functions may help interpret a situation that is being modeled. The three approaches provide a means of organizing algebra content that goes beyond building up layers and layers of procedures.

Although several conceptually-oriented textbooks exist for developing algebraic ideas with children, analogous materials for use with preservice teachers are not easy to find. Algebra textbooks do exist for college students, but they are typically designed to prepare students for subsequent mathematics courses, not to prepare preservice teachers for the mathematics classroom, and they do not necessarily contain the topics in our framework. Lacking a tailor-made textbook, we resolved the issue by selecting a nontraditional college algebra textbook (one that emphasizes a functions-and-modeling approach to algebra) and then supplementing it with exemplary elementary and middle school curriculum materials, including algebra modules from *Connected Mathematics* (Lappan, Fey, Fitzgerald, Friel, & Phillips, 1998a, b, c, and d) and *Mathematics in Context* (National Center for Research in Mathematical Sciences Education & Freudenthal Institute, 1998).

This investigation focused on the role of these exemplary curriculum materials in serving the goals of our algebra course for preservice teachers. The research addressed the following questions: (1) What aspects of preservice teachers' knowledge of algebraic concepts are revealed in their use of exemplary curriculum materials designed for middle school students? (2) What aspects of preservice teachers' focus on children's algebraic reasoning are revealed in their use of these materials? and (3) What are preservice teachers' views about the nature of algebra before and after the course?

### Method

The participants in this investigation were 30 elementary education majors enrolled in an algebra course for preservice elementary and middle school teachers who had chosen mathematics as their area of specialization. Five of these preservice

teachers also indicated plans to complete a middle school mathematics endorsement. All of the preservice teachers had successfully completed two years of high school algebra and 13 had successfully completed a year of high school calculus. All of the preservice teachers were juniors or seniors and had completed the two-course sequence of mathematics required of all elementary education majors. Only two of the preservice teachers had taken a mathematics teaching methods course. For the 26 preservice teachers who had taken the SAT exam, the median mathematics score was 560.

On the first day of class, the preservice teachers wrote their responses to the question, "What is algebra?" They answered the same question again on the last day of class. The class spent the first four weeks investigating patterns and solving problems selected from the NCTM Algebra *Navigations* series (Cuevas, Yeatts, & House, 2001), Driscoll's (1999) *Fostering Algebraic Thinking: A guide for teachers, grades 6-10*, and algebra modules from *Connected Mathematics* (Lappan et al., 1998c) and *Mathematics in Context* (National Center for Research in Mathematical Sciences Education & Freudenthal Institute, 1998).

In the second week of the course, the preservice teachers read and discussed the article, "A Foundation for Algebraic Reasoning in the Early Grades" (Yackel, 1997). This article describes a classroom discussion in which at least one student moves from a focus on isolated cases to reasoning about the entire range of possibilities. Then each preservice teacher wrote responses to a series of questions.

During this time, the class spent three days exploring *Comparing Quantities*, a sixth-grade algebra module from *Mathematics in Context* (National Center for Research in Mathematical Sciences Education & Freudenthal Institute, 1998). After working through sections of the module in groups, the preservice teachers completed the Chickens problem (p. 21) individually as an in-class quiz. The following day, the class examined the various strategies used to solve the Chickens problem. Then they received an interview assignment to pose the Chickens problem to a child in grades 4-8 and to ask questions to elicit as much information as possible about the child's mathematical thinking. Each preservice teacher then completed a written analysis of his or her interview with the child.

The class then spent three days exploring various sections of *Say It with Symbols: Algebraic Reasoning*, an algebra module for grade 6 from the *Connected Mathematics* series (Lappan et al., 1998c). Preservice teachers completed Problem 3.3: Finding the Area of a Trapezoid and follow-up questions (pp. 40-41) as a quiz.

In the fifth week, the class began a ten-week exploration of functions and modeling. Throughout this time, the class alternated its focus between selected investigations of linear, exponential, and quadratic functions in *Connected Mathematics* algebra modules and corresponding lessons in the college algebra textbook. They investigated linear relationships in *Thinking with Mathematical Models* (Lappan et al., 1998d), exponential relationships in *Growing, Growing, Growing* (Lappan et al., 1998b), and

quadratic relationships in *Frogs, Fleas, and Painted Cubes* (Lappan et al., 1998a). The class spent two or three days with each module and completed a quiz after each one.

The last three weeks of the semester were devoted to matrices and investigations of algebraic structure. This investigation does not focus on that part of the course.

### Research Findings

#### Preservice Teachers' Understanding of Algebraic Concepts

For this investigation, samples of the preservice teachers' work were collected to reflect each of the three conceptual approaches to algebra adapted from Bednarz, Kieran, and Lee (1996): generalization, problem solving, and functions and modeling. The data sources for examining preservice teachers' understanding of algebraic concepts included: (1) solutions to the Area of a Trapezoid problem, (2) solutions to the Chickens problem, and (3) solutions to quizzes focusing on linear, exponential, and quadratic functions.

#### Generalization

Generalization is described by Bednarz, Kieran, and Lee (1996) as focusing on the construction of formulas that account for general procedures or relationships among quantities. The Area of a Trapezoid problem in *Say it With Symbols* (Lappan et al., 1998c) provides an opportunity to assess preservice teachers' reasoning about relationships among geometric quantities. This problem asks students to interpret four hypothetical children's methods for finding the area of a trapezoid. Table 1 shows preservice teachers' success with the various tasks associated with the problem. Task 4 presented the greatest challenge. Preservice teachers struggled with creating a drawing to match the expression  $\frac{1}{2}h(b-a) + ha$  to illustrate finding the area of a trapezoid.

#### Problem Solving

Bednarz, Kieran, and Lee (1996) define the problem-solving approach as solving problems by forming and solving equations using letters as unknowns. The Chickens problem, from the sixth-grade *Comparing Quantities* (National Center for Research in Mathematical Sciences Education & Freudenthal Institute, 1998), depicts a situation involving three unknown quantities, the weights of three different chickens. This problem asked students to examine a series of three drawings, each showing a different combination of two of the three chickens in the problem. Given the total weight for each pair of chickens, the problem is to find the weight of each individual chicken. A possible solution strategy is to set up and solve a system of three equations involving three variables. Sixth-graders, though, would be more likely to guess and check or to employ informal reasoning skills to analyze the various relationships among the three unknown quantities. The latter of these two strategies would be considered more algebraic even though the formal procedures of algebra may not be visible. Of the pre-

**Table 1.** Preservice Teachers' Success With Various Tasks Associated With The Area Of A Trapezoid Problem

| Tasks  | Number of PSTs<br>(n = 30)* |    |
|--|-----------------------------|----|
|  | Yes                         | No |
| 1. Given labeled drawings of trapezoids, explain the methods for finding area.             | 27                          | 3  |
| 2. Write an expression to describe each method.  | 25                          | 5  |
| 3. Show that the expressions are equivalent.   | 26                          | 4  |
| 4. Given an expression, make a drawing and use it to explain the method for finding area.* | 6                           | 13 |
| 5. Explain why one expression is equivalent to the other three.*                           | 13                          | 6  |
| 6. Find the area of a given trapezoid using each of the four expressions.*                 | 17                          | 2  |

\* Only 19 students attempted Tasks 4-6, perhaps because these were offered as bonus questions.

service teachers in this investigation, 8 set up and solved a system of three equations, 13 used informal reasoning skills, and 9 relied on guess and check. All but 2 preservice teachers successfully solved the problem.

### Functions and Modeling

The functions and modeling approach focuses on various representations of dependence relationships among real-world quantities (Bednarz, Kieran, & Lee, 1996). In each investigation, the class modeled real-world situations and examined how the change in one variable related to change in a second variable. For each situation, they explored connections among tables, graphs, and equations. The responses to quiz questions taken from *Connected Mathematics* (Lappan et al., 1998a, b, & d) algebra modules provide evidence of some of preservice teachers' strengths and weaknesses regarding functions and modeling. Tables 2, 3, and 4 reveal preservice teachers' success with various tasks associated with linear, exponential, and quadratic functions, respectively.

### Linear Functions.

Table 2 shows that more than a third of the preservice teachers had difficulty writing adequate explanations for how to determine a linear relationship from either a table or an equation. Additionally, more than a third failed to write an equation to match the graph of a line.

### Exponential Functions

As shown in Table 3, only a third of the preservice teachers adequately described the exponential pattern of change in a given table. When given the equation  $y = 2(3^x)$  only three preservice teachers correctly identified 200% as the rate of growth. Most preservice teachers said the rate of growth was 300%, evidently confusing the "rate of growth" with the "growth factor," even though the curriculum module carefully distinguishes between the two concepts.

**Table 2.** Preservice Teachers' Success With Various Tasks Associated With Linear Functions

| Tasks  | Number of PSTs<br>(n = 30) |    |
|--|----------------------------|----|
|  | Yes                        | No |
| 1. Recognize linear relationships from tables.                           | 28                         | 2  |
| 2. Explain how you can recognize a linear relationship from a table.     | 18                         | 12 |
| 3. Recognize linear relationships from equations.                        | 27                         | 3  |
| 4. Explain how you can recognize a linear relationship from an equation. | 17                         | 13 |
| 5. Recognize linear relationships from graphs.                           | 30                         | 0  |
| 6. Given a graph, write an equation.                                     | 18                         | 12 |
| 7. Explain how you can recognize a linear relationship from a graph.     | 28                         | 2  |
| 8. Find an equation passing through two points on a graph.               | 26                         | 4  |
| 9. Given a point and the slope, find an equation of the line.            | 26                         | 4  |
| 10. Given a situation, make a table.                                     | 28                         | 2  |
| 11. Given a situation, make a graph.                                     | 29                         | 1  |
| 12. Write an equation to describe the situation.                         | 26                         | 4  |

**Table 3.** Preservice Teachers' Success With Various Tasks Associated With Exponential Functions

| Tasks   | Number of PSTs<br>(n = 30) |    |
|---|----------------------------|----|
|   | Yes                        | No |
| 1. Given a exponential situation, create a table.   | 23                         | 7  |
| 2. Describe the pattern of change in a table.   | 10                         | 20 |

| 5. Given two equations, determine in which equation the y value increases at a faster rate.         | 30                         | 0  |
| 6. Given an exponential equation, determine the initial value of the function.                      | 28                         | 2  |
| 7. Given an exponential equation, determine the rate of growth.                                     | 3                          | 27 |
| 8. Given tables, distinguish between a constant rate of increase and a percentage rate of increase. | 26                         | 4  |

### Quadratic Functions

As Table 4 indicates, all but three preservice teachers were able to draw and label the rectangle represented by a quadratic equation, but a third of the preservice teachers failed to label the area of the rectangle. A more serious difficulty appeared in Tasks 9 and 10, in which preservice teachers struggled to extend a geometric pattern and to write the equation representing the pattern.

### Preservice Teachers' Focus on Developing Children's Algebraic Reasoning

The data sources for assessing preservice teachers' focus on the development of children's algebraic reasoning were: (1) their responses to questions about "A Foundation for Early Algebraic Reasoning in the Early Grades" (Yackel, 1997) and (2) their analyses of the Chickens problem interview.

### Responses to Yackel Article

The Yackel (1997) article seemed to provide preservice teachers with a language for describing algebraic reasoning. After reading the Yackel article, 16 of the 28 preservice teachers who completed the article response mentioned "patterns" or "relationships" in their answer to the following: "Describe the type of thinking that forms the foundation for algebraic reasoning in the elementary grades. How is this type of

**Table 4.** Preservice Teachers' Success With Various Tasks Associated With Quadratic Functions

| 4. Label the areas of the rectangle represented by a quadratic equation.      | 19                         | 11 |
| 5. Recognize quadratic relationships from tables.                             | 29                         | 1  |
| 6. Explain how you can recognize a quadratic relationship from a table.       | 24                         | 6  |
| 7. Write an equation for each table that represents a quadratic relationship. | 24                         | 6  |
| 8. Given a situation, determine a specific value of the quadratic function.   | 26                         | 4  |
| 9. Extend a quadratic geometric pattern.                                      | 18                         | 12 |
| 10. Write an equation to describe a quadratic geometric pattern.              | 15                         | 15 |

thinking different from numerical reasoning?" Interestingly, though, the remaining 12 preservice teachers used language that suggested they equate algebraic reasoning with the process of problem solving (not to be confused with a problem-solving approach to algebra). In their descriptions of algebraic reasoning, these 12 preservice teachers mentioned such things as the importance of recognizing multiple solutions and having students explain their solution strategies, but did not refer to anything specifically algebraic.

#### **Chickens Problem Interview**

Yackel (1997) places emphasis not on the content of algebra, but rather on "the underlying thinking and reasoning of the students" (p. 276). Thus, in order for preservice teachers to develop a coherent view of algebraic reasoning, it is important to

provide opportunities for them to examine children's mathematical thinking. Indeed, Fennema and Franke (1992) suggest that knowledge of students' cognitions is more valuable to teachers than knowledge of learning theories. McGowen and Davis (2001) suggest that a way in which preservice teachers can become more effective teachers of early algebra is by seeing children solve problems with which they themselves have struggled. The Chickens problem interview was designed to serve this purpose.

The instructions asked preservice teachers to: (1) describe the student's work with the problem, noting questions asked and strategies attempted, and (2) discuss conclusions about the child's mathematical thinking. Unfortunately, because the instructions did not ask preservice teachers to focus on "algebraic reasoning," it is not appropriate to analyze their descriptions of algebraic reasoning. However, 13 of the 28 preservice teachers who completed this assignment carefully described the child's solution and discussed aspects of the child's algebraic reasoning. Another 9 preservice teachers mentioned algebraic reasoning, but did not provide a specific description. Finally, 6 preservice teachers focused entirely on other issues such as the child's attitude toward mathematics. The instructions also asked preservice teachers to reflect on the interview, describing what they would do differently another time. Eleven preservice teachers responded by saying they would ask more and better questions. Four said they would provide less help, and two said they would provide more help. Four preservice teachers said they would like to interview more children to get a broader perspective.

### **Preservice Teachers' Views about the Nature of Algebra**

The data sources for analyzing preservice teachers' views about the nature of algebra were their initial and terminal responses to "What is algebra?" Preservice teachers' responses to the question, "What is algebra?" were assigned to the following categories: symbolic, problem solving, generalization, and functions. The latter three categories are derived from the three conceptual approaches to algebra adapted from Bednarz, Kieran, and Lee (1996). For coding purposes, *symbolic* responses merely listed various symbols and operations, *problem solving* focused on solving equations, *generalization* mentioned patterns or relationships, and *functions* included the word "functions" or mentioned connections among tables, graphs, and equations. Table 5 shows preservice teachers' responses on the first and last days of class. At the end of the course, none of the students indicated a symbolic view of algebra, instead expressing some combination of generalization, problem solving, and function definitions.

### **Conclusion**

The results of this investigation show that exemplary curriculum materials developed for middle school students present mathematical challenges for some preservice elementary and middle school teachers. Preservice teachers in this investigation were challenged by situations involving generalization, problem solving, and functions. Although most found answers for problems involving linear relationships, the preser-

\* Some preservice teachers' responses reflected more than one definition of algebra

vice teachers were often unable to explain their thinking. They had difficulty answering questions about the rate of change of exponential and quadratic functions. However, they were sometimes bored by materials designed for elementary and middle school students. Preservice teachers often struggle to clearly communicate their understanding of the mathematical relationships embedded in the activities, but they do not always need to explore the same concept from as many angles as are presented in the well-developed materials. We are compelled to use the materials judiciously, selecting critical elements of the activities but avoiding over-repetition.

The interview situation with children proved to be an effective tool for helping preservice teachers begin to focus on children's mathematical thinking, and exemplary curriculum materials offer engaging problems for this purpose. Many of the preservice teachers in this investigation did not provide evidence that they understand the difference between algebraic reasoning and problem-solving skills. Even more discussion may be needed to help preservice teachers strengthen their understanding of what constitutes algebraic reasoning, and more than one of these interview experiences may be necessary to help preservice teachers shift their focus from children's problem-solving behaviors to children's algebraic reasoning.

As they experience exemplary curriculum materials from a learners' point of view, preservice teachers can begin to think about them from a teacher's perspective. It is important to take time to discuss the philosophy that guided the development of reform curricula so that preservice teachers will understand why these materials are so different from the textbooks with which they are more familiar. With guidance, they may come to appreciate the potential of the new curricula for developing children's mathematical thinking.

Before they can successfully promote algebraic thinking in their own classrooms, preservice teachers need to understand algebra as a way of thinking, a way of working with the patterns that occur every day. A comparison of their initial and terminal

responses to the question “What is algebra?” suggests that this group of preservice teachers broadened their views about the nature of algebra. Because their terminal definitions of algebra reflect the three conceptual approaches to algebra adapted from Bednarz, Kieran, and Lee (1996), it would seem that these approaches do indeed serve as a meaningful structure for framing the course. Providing an opportunity to explore exemplary elementary and middle school curricula in the context of a college algebra course has helped preservice teachers develop a dynamic vision of algebra they can take with them into the classroom.

## **VIEWING A REFORM-BASED MATHEMATICS CURRICULUM THROUGH THE EYES OF TWO VETERAN TEACHERS**

Ann Wallace

awallace@calumet.purdue.edu

Miriam Gamoran Sherin  
Northwestern University  
msherin@northwestern.edu

The focus of this research is an investigation of the ways that teachers use reform-based mathematics curriculum materials. Specifically, we explore how two veteran elementary-school teachers make use of a new curriculum that they volunteered to implement for two consecutive years. Based on observations of instruction and interviews with the teachers, we examine the extent to which the teachers relied on information in the written curriculum materials to guide their instruction, and their reasons for doing so. Furthermore, we consider how the teachers' approaches to curriculum use changed over the two-year period. We found that one teacher followed the curriculum quite closely during the first year and more flexibly during the second year. In contrast, the other teacher used the curriculum liberally during the first year, and followed it much more closely during the second year. Discussions of similarities and differences in the teachers' implementation of the curriculum give rise to important implications for curriculum development in the context of reform.

Recently, researchers and mathematics educators have called for curricula that not only support student learning, but also help teachers learn to manage the demands of reform (Ball & Cohen, 1996; Remillard, 1999). In turn, several new mathematics curricula have been developed that strive to be educative for teachers. They include, for example, information on possible student misconceptions, explicit explanations of curricular goals, and discussions of key mathematical concepts. At the same time, however, these curricula look quite different from the traditional materials that teachers have used and as a result may require that teachers develop new approaches to curriculum use.

In this research, we address this issue by attempting to characterize the ways that teachers use reform-based curriculum materials. In particular, we examine the experiences of two veteran elementary-school teachers who implemented a reform-based mathematics curriculum over the course of two years. For each teacher, we illustrate the specific approach that the teacher had towards using the curriculum materials, paying particular attention to how closely the teachers chose to follow the written curriculum and the reasons behind their decisions to do so. In addition, we describe the ways in which the two teachers' approaches to curriculum use changed from year one to year two.

### **Theoretical Perspective**

Two perspectives on the relationship between teachers and curricula help to frame this research. First, prior research emphasizes that curricula do not always dictate

instruction (Sosniak & Stodolsky, 1993). Instead, it is teachers who bring these materials to life in the classroom, and the “enacted curriculum” often differs from what was in the “written curriculum” or teacher’s guide (Ben-Peretz, 1990). Along these lines, Freeman & Porter (1989) identified several different styles of textbook use among teachers. Particularly relevant for this study was their description of some teachers as “textbook bound,” closely following the textbook, while other teachers relied less heavily on the details of the curriculum.

Second, and more recently, researchers have begun to examine teachers’ use of curricula in the context of mathematics education reform (Heaton, 2000; Lloyd, 1999; Remillard, 1999, 2000). Some of this work examines the opportunities for learning that occur as teachers use reform-based materials (Davenport, 2000; Remillard, 1999; Sherin, *in press*). These researchers describe the process through which using a new curriculum helps teachers to increase their knowledge of both content and pedagogy. In addition, their work highlights that this learning can take place as teachers use the new materials with students, and as teachers reflect on these materials outside of the demands of instruction.

Other research in this area explores differences in teachers’ approaches to reading, evaluating, and adapting reform-based curriculum materials (Morse, 2000; Remillard, 2000; Sherin & Drake, 2000). Common to all of these approaches is the notion that teachers do in fact develop particular approaches to using new curricula. For example, researchers have described a number of different ways that teachers “read” reform-based materials. Remillard, for instance, (1999) contrasts one teacher who read the curriculum by focusing on the activities for students with a second teacher who read the curriculum in order to get a general idea of the mathematical goals for each lesson. Similarly, Sherin and Drake differentiate between teachers who read for the “big ideas” of a lesson versus teachers who read for lesson details, looking at the precise wording of examples and explanations. Morse also discusses how teachers read reform-based curriculum materials. She emphasizes the need for teachers to learn to read the curriculum in ways that help them understand the intentions of the curriculum designers. These different findings highlight the wide variety that exists in the ways that teachers use new reform-based curriculum materials. Furthermore, examinations of how and why teachers develop these different approaches suggest that curriculum use is influenced by teachers’ understandings of the purpose of the curriculum materials and by their goals for instruction.

### **Research Design**

This research is part of a project that investigates and supports teachers as they implement the reform-based mathematics curriculum Children’s Math Worlds (CMW). The first- through third-grade CMW curriculum is designed to incorporate the best of both traditional and reform mathematics curricula by attending both to children’s natural solution methods and to effective standard procedures. Furthermore, the cur-

riculum builds on the individual experiences, interests, and mathematical knowledge that diverse children bring to their classrooms. Specifically, CMW is based on combining the following three key features: (a) representational and conceptual supports to facilitate individual understanding, (b) developmental sequences of conceptual structures, and (c) real-world contexts for exploring mathematical thinking (Fuson, De La Cruz, Lo Cicero, Smith, Hudson, Ron et al., 2000). The design of CMW creates new challenges for many elementary-school teachers of mathematics because using this curriculum is very different from using a traditional mathematics textbook.

CMW includes a variety of materials for teachers and students. First, there is a teacher's guide with detailed information about each lesson, as well as an overall description of every unit and suggested participant structures for organizing classroom instruction. There is also a book for students with worksheets and activities related to each lesson. In addition, CMW provides an assessment packet and a set of innovative classroom manipulatives to use during instruction.

This study investigated the curriculum use of two veteran elementary-school teachers, Cindy and Tracy, in a large urban public school district where the CMW materials were being field-tested. The study began when Cindy and Tracy implemented the materials for the first time (1999-2000). Both teachers had previously been involved with mathematics education reform and were interested in trying out additional materials that might help their students. At the beginning of the study, the second-grade teacher (Cindy) had been teaching elementary school for 18 years. She was recommended by the acting assistant principal and stated that if mathematics was headed away from traditional instruction, she wanted to be prepared. She was observed monthly during her first year of using CMW and on two consecutive days at the beginning, middle and end of the second year.

The third-grade teacher (Tracy) was in her 20<sup>th</sup> year of teaching. She had previously implemented a reform-based curriculum for one year, and was described by the school's curriculum coordinator as a teacher who was willing to try to meet the goals of reform. Tracy was observed monthly during the first year (except for two months) and on two consecutive days at the beginning and middle of the second year. Both teachers also participated in post-observation interviews and in monthly meetings with a researcher. During these interviews and meetings, the teachers were invited to reflect on the recent events of their classrooms. In particular, they were asked questions about decisions they had made regarding how they were enacting the curriculum. For instance, if either teacher omitted part of a lesson, the meetings were a place for them to elaborate on their reasons for doing so. In addition, the teachers were encouraged to discuss any questions they had concerning the goals of lessons they had recently taught. All observations, interviews, and meetings were videotaped and transcribed.

Fine-grained analysis was used to characterize how each teacher incorporated the reform-based curriculum into their mathematics instruction (Schoenfeld, Smith,

& Arcarvi, 1993). To do this, transcripts of classroom video were analyzed alongside the corresponding CMW lesson to determine the extent to which each teacher either deviated from or followed the lessons as written in the curriculum. As a result, similarities and differences among the written and enacted lessons were noted in several areas including the mathematical ideas that were discussed in class, the order in which activities were implemented, and the vocabulary, explanations, and representations utilized by the teacher. Interview and meeting transcripts were also coded, citing the teachers' reasons for the choices they made as they read and implemented the CMW lessons. Based on this analysis, we characterized each teachers' approach to curriculum use in their first and second years of using the new materials.

### **Results**

Analysis of the data revealed that each of the teachers demonstrated a consistent approach to using the curriculum in the first year of the study. These two approaches, however, were quite different from one another. Furthermore, during the second year of the study, the teachers also demonstrated a consistent approach to using the materials. Yet for each teacher this approach differed from how the teacher had used the curriculum during the previous year. In what follows, we discuss each teacher in turn.

#### **The Case of Cindy**

The first year that Cindy implemented CMW, she followed it very strictly. She began with Unit 1, Lesson 1, and from there, implemented each lesson in the order that it was presented in the teacher's guide. Furthermore, Cindy paid close attention to the details of each of these lessons, planning to use all of the suggested activities. She described this approach as wanting to go "straight through everything," and claimed that "I don't think there's anything I don't use." In particular, Cindy carefully read the example problems given in the curriculum materials, and often used them precisely as they were written. She also studied the sample questions provided by the curriculum as potential probes that she could use to encourage students to share and explain their thinking. During instruction, Cindy tended to use these probes exactly as they appeared in the curriculum materials. In fact, during an interview, Cindy noted that these questions were an important part of her instruction, explaining that "the scripted part ... it helps me."

The following example is typical of how Cindy used CMW in the first year of the study. On this day, Cindy was implementing a lesson from Unit 1. The lesson began, as did many of the CMW lessons, with two simultaneous activities, "Quick Practice" and "Homework Check." The idea was for student leaders to conduct practice activities with the class, while the teacher checked the students' homework. Cindy's class had done "Quick Practice" on several occasions prior to this lesson, and thus the students were familiar with a range of practice activities. Nevertheless, Cindy asked a pair of students to lead the class in the two practice activities ("Teen Routines" and "Finger

Flash”) that were specified in the day’s lesson. The students were given explicit directions that these were the activities listed in the curriculum and that is what they would do today.

The next part of the lesson involved having students solve addition word problems. Several example problems were given in the teacher’s guide with the objectives stating that students should explore two specific solution strategies: (a) counting on, and (b) counting up. Cindy followed the directions in the teacher’s guide precisely and read the story problems verbatim from the teacher’s guide. Moreover, as the curriculum suggested, she required her students to illustrate their solutions by using both the ‘counting on’ and ‘counting up’ methods of addition. For instance, when solving the problem: *I have 11 gumdrops, and I grouped them by flavor. I put the 3 lemon ones in my mouth and the cherry ones in my pocket. How many cherry gumdrops do I have?*, the first student called upon shared the “counting up” method. Therefore, Cindy next called for a student who used the “counting on” method to explain to the class what she had done.

In addition to the close attention that Cindy gave to each activity in the day’s lesson, she also worked more broadly throughout the lesson to satisfy other recommendations that she had read in the teacher’s guide and that she viewed as central to implementing CMW. For example, the curriculum encouraged the teacher to allow students to display multiple solution methods. Therefore, in preparing to teach this lesson, Cindy make sure that students would have a way to display how they solved each problem. To do so, she decided to pass out individual chalkboards for her students to use to record their methods. This helped Cindy to easily monitor individual student’s solutions and then to choose students with different methods to stand before the class and explain their solutions. Furthermore, after students demonstrated the ‘counting on’ and ‘counting up’ methods, Cindy asked students if there were other solution strategies that they could use to solve the problem, and on several occasions, students demonstrated the “make a 10” strategy that had been introduced in a previous lesson. Thus, Cindy worked to meet the specific goals of the day’s lesson — to have students use the ‘counting on’ and ‘counting up’ strategies — but at the same time she took seriously the suggestion in the lesson to have students “display multiple strategies.”

Similarly, Cindy attempted to follow the curriculum’s recommendation to promote a “Math Talk” community where students as well as the teacher asked questions of each other and offered explanations for each others’ solutions. Thus, as students explained their solutions in front of the class, Cindy facilitated a discussion, encouraging students to talk about their own and others’ ideas. For example, at one point during the lesson, Cindy asked a student to elaborate the “make a 10” method that he had used to solve the problem  $8 + 9$ . The student responded, “I took 2 [from the 9] and added it to the 8, and  $8 + 2$  equals 10. Then I took the 7 [left] and added it to 10 and  $10 + 7$

is 17.” Following this explanation by the student, Cindy turned to another student and said, “David, can you say what Anthony just said? How did he get his answer?”

Also in line with the goals of the curriculum, Cindy tried to use student errors as learning opportunities for the class. Thus, on this day, when one student presented a solution that was incorrect, Cindy used the error as an opening to discuss with the class a variety of misconceptions that students had concerning order of operations. Cindy explained that in previous years, she tended to simply correct students’ mistakes and continue with the lesson-in-progress. This year, however, she was working to achieve the goals of CMW one of which involved discussing errors that arose with the class.

As illustrated in this example, throughout the day, Cindy worked with her students so that the lesson unfolded during instruction as it appeared to her in the teacher’s guide. She did not deviate from the lesson plan with additional problems for students to solve, and instead kept the central goals of the lesson and of the curriculum at the forefront of her plans. Overall, Cindy’s approach to using the curriculum during the first year was to follow it as closely as possible.

In her second year of implementing CMW, Cindy demonstrated a different approach to using the materials. In particular, she used the curriculum much more flexibly than she had in the first year. While she continued to follow the general order of topics as they were presented in the curriculum, she would, at times, skip a lesson entirely, or skip parts of a lesson that she felt were “too repetitive.” Despite adapting the materials, the lessons that she taught still conformed to the goals of the curriculum. Cindy explained that she had a sense now of what students were supposed to learn and so she used that knowledge to decide which parts of a lesson to implement.

For example, during a lesson that involved buying items with pennies, nickels, and dimes, Cindy felt comfortable skipping an entire section of the lesson which ‘introduced the nickel.’ In an interview following that particular lesson she stated that the students were already familiar with the nickel and therefore she did not feel it was necessary to go over that particular section with the class. “They’ve already used the quarter, so I figured they already knew the nickel part...and I’ve had them count by fives [already].” Thus, Cindy was aware of her students’ understandings and felt that she could still meet the goals of the lesson whether or not she used that particular activity.

At other times, Cindy adapted a lesson not by omitting an activity, but instead by modifying an activity from the way that it was described in the teacher’s guide. For instance, the curriculum introduced a manipulative called “penny strips” to help students work with monetary amounts. On one day, Cindy decided to make a set of large penny strips which she laminated and attached to magnets. She then placed the new penny strips on the board in the front of her classroom. This was not a suggestion found in the curriculum, yet it was something that Cindy believed would enhance her presentation of the lesson. Using the large penny strips, Cindy demonstrated on the

chalkboard how she expected students to use the smaller penny strips at their seats. Furthermore, she used the over-sized penny strips to work with students on the concepts they were exploring in the day's lesson. She stated afterwards, "...they could see the [money] better, instead of me drawing it, with my [penny] board."

Similarly, in the same lesson, Cindy replaced a "Quick Practice" activity with an activity that was designed to come later in the lesson. The "Quick Practice" activity involved students working in pairs. In an interview following the lesson, Cindy explained that while she regretted not having enough time for students to work in pairs as was suggested in the curriculum, she felt confident that she had met the goals of the lesson through the activities that she had used.

Thus, during the second year of the project, Cindy developed a much more flexible approach to using the CMW materials. Her overarching goal at this point was to help students learn the mathematical ideas of the lessons, and she felt able to do so while adapting the materials somewhat. She still saw herself as implementing CMW, but she had taken more control over the specifics of what that might look like during instruction.

### The Case of Tracy

During her first year of implementing the new curriculum, Tracy used CMW as one of several resources that guided her instruction. She explained, "Sometimes I like to just read [the CMW materials] and then have my own ideas. [I] pick...up some of the ideas...I try to make notes in the margin combining my ideas and [the CMW ideas.]" Thus, Tracy would use CMW to learn the main objective for a given lesson, but would then pick and choose pieces of the CMW lesson to implement along with other materials she had used in the past.

For example, during one lesson addressing story problems, Tracy used the initial activity suggested by CMW but then switched to a more familiar method of discussing addition and subtraction story problems. The lesson centered on a Problem Bank of story problems found in the curriculum. Tracy gave the subtraction problem: *Kamal weighs 67 pounds. His older brother Osama weighs 110 pounds. How much more does Osama weigh than Kamal?* The students had a difficult time when they tried to determine how to arrange the numbers in order to perform the necessary computation. Some students recorded the problem correctly as  $110 - 67$ , but then either subtracted incorrectly (the minuend from the subtrahend) or added the numerals. Other students recorded the problem incorrectly as  $67 - 110$  and could not figure out how to perform the subtraction based on how it was numerically written. Because of the difficulties her students were having, Tracy made the decision to stop the current lesson and to address the issue in a manner she felt would be beneficial to her students. She summoned the students away from their seats to the floor in the center of the room and held a 'mini-lesson' to review how to determine the order of numbers and which arithmetic operation (addition or subtraction) to use when solving certain story problems. It was

not uncommon for her to take this approach. When her students did not seem to be grasping the concept, Tracy often stopped the current lesson to review the key mathematical ideas involved.

As a part of the mini-lesson, Tracy rewrote the story problem so that Osama's weight was given first, and then Kamal's weight was given. Tracy then asked her students if anyone knew which number should be written first in a subtraction problem. In response, a student explained that 110 would "go on top" and when Tracy asked, "Why?" the student continued by stating that "the higher number goes on top in a subtraction problem." Tracy further asked how the class could decide if they were supposed to add or subtract the numbers in the problem. Students seemed unsure, and thus Tracy directed the students to the key words 'more than.' In response, a student mentioned that 'more than' means take away so that meant it was a subtraction problem.

During this mini-lesson, Tracy relied on instructional strategies that were not suggested in the CMW materials, but rather, were based on techniques that she had used previously. Specifically, her idea to reorder the numbers in the problem was based on her prior experience that ordering the numbers in the problem in the same way that they will appear in the computation helps students to record the numeric computation accurately. Specifically, she stated, "It's confusing [for the children] when the numbers in the [story] problem are in a different order [than in the numeric computation.]" Furthermore, the key word strategy was also a technique that Tracy had used in the past when helping students learn to solve story problems. Thus, this example shows that Tracy was not tied to using the CMW curriculum. She was willing both to use different kinds of activities with her students, and to help them learn the lesson objectives in ways other than those specifically suggested in the teacher's guide. Tracy was aware of her willingness to adapt the curriculum in these ways. In fact, in an interview she stated, "It's up to me, right? I mean, I could have reworded [the problem] or something like that." In all, Tracy was comfortable supplementing a lesson, in particular when she believed that her students were struggling with the mathematical ideas in the lesson.

Interestingly, during the second year that Tracy used CMW, she followed the curriculum more closely and did not generally look to other resources to teach the CMW topics. When asked how the second year compared to using the curriculum in the first year she stated, "I know it! I kind of know the whole routine... Last year I would bring in other materials and I wasn't familiar with [CMW] enough to know how it would work... Last year I wanted to get away from [CMW] and do it the way I understood it. But now that I understand [the curriculum] better, I'm doing very little adapting." Tracy also stated that having taught the curriculum the previous year helped her to understand her students' responses. She stated, "Compared to last year [I] can hear their mistakes better. I can see their mistakes on the board."

For example, during the second year of the study, Tracy taught a lesson on quadrilaterals whose purpose was for students to explore different four-sided shapes such

as squares, rectangles, parallelograms, and rhombi. When Tracy taught this lesson the previous year (during her first year of implementing CMW), she did not use the activities suggested by CMW to help students explore the quadrilaterals given in the lesson. Instead, she focused the lesson on the definitions of the different shapes, and on having students provide a name for each of the shapes given on the students' pages. For example, Tracy was content if her students labeled a figure with four equal sides and four right angles as only a *square*. She did not make the connection for her students that this definition also described a *rhombus* nor did she discuss with the class why such a definition might describe more than one kind of shape. During this lesson, Tracy also omitted the section addressing the heights of the quadrilaterals. This was an additional concept included in the objectives.

In contrast, during the second year, Tracy implemented this lesson quite differently, sticking closely to the activities suggested in the lesson in order to meet the lesson objectives. For example, as outlined in the teacher's guide, Tracy asked students to compare different shapes and to try to define the relationship between a rectangle and a square and between a square and a rhombus. Students responded by making a variety of observations, including the following comparison made by Ravi: "A square has four equal sides and the corners [are] equal, all four corners [are] equal. A square is like a ...rhombus." In addition, Tracy followed the curriculum's recommendation to have students compare the angles in the different shapes, the heights of the different shapes, as well as the relationship between the lengths of the sides of a given shape. As described in the curriculum, Tracy also provided students with toothpicks that they could use to compare the lengths and angles of the different shapes.

Tracy's implementation of this lesson during the two years was quite different. Specifically, during the first year, Tracy taught a lesson on the topic of quadrilaterals, but did not make much use of the suggested CMW activities. During the second year, however, Tracy taught the lesson by attempting to stick closely to the way that it was written in the teacher's guide. This same pattern was evident throughout the second year, with Tracy consistently implementing CMW with more fidelity than she had during the first year. Overall, during the second year of the study, Cindy felt better able to use the CMW activities to try to meet the needs of her students.

### Discussion

Each of the teachers demonstrated a particular approach to using the curriculum in the first year of the study. Cindy's approach involved closely adhering to all aspects of the CMW lessons — from using the activities provided to using the language suggested for talking with students. In contrast, Tracy used the CMW curriculum materials as more of a general guide for information about the topic of the lesson that she would teach. She tended to use some parts of the CMW lesson, the students' pages for example, but also regularly incorporated activities that she had used in the past to teach what she believed to be the lesson objectives.

Despite these differences, however, there were important similarities among the reasons for the teachers' approaches to using the curriculum. Specifically, in their first year of using the curriculum, both teachers felt that they did not have a deep understanding of the goals behind the daily lessons and related activities. Yet, this influenced the two teachers' instruction in different ways. Cindy felt that she did not know enough to make appropriate changes in the materials and therefore needed to carefully follow all aspects of the curriculum. In contrast, Tracy decided that because she did not know how a CMW lesson would proceed, it did not make sense for her to implement the lesson as planned. It was for this reason that she used CMW activities along with other materials that she had used in the past.

In the second year of the study, both teachers claimed to have developed a deeper understanding of the purpose of the curriculum and their approaches to curriculum use changed accordingly. Still, as before, there were differences in the particular ways that this greater understanding of the curriculum influenced the teachers' instruction. Specifically, Cindy began to regularly adapt the CMW lessons claiming that she could do so because she now understood "where a lesson was headed." In contrast, Tracy began to use the curriculum with more fidelity explaining that she could now see how the curriculum worked and therefore was willing to follow it more closely. Interestingly, despite the fact that these changes were in opposite directions — Cindy implementing the curriculum with less fidelity and Tracy implementing the curriculum with more fidelity — the teachers' practices had become somewhat similar. They both followed the general outline of the curriculum. Furthermore, while they used most of the activities described for each lesson, they also made changes in light of the needs of their students. This research suggests that while teachers may exhibit broad differences in their initial use of new curriculum materials, by the second year of implementation, their practice can be similarly guided by an understanding of the goals of the materials. Future research is examining the extent to which the teachers' practices during the second year aligned with the goals of reform.

### Conclusions and Implications

Generally, when we talk of curricula as being educative for teachers, we think of particular aspects of a lesson that can help a teacher to understand the reasons behind the curriculum designers' intentions or that can help a teacher to predict how students might respond to a specific lesson. Based on this research and on the work of our colleagues (Drake & Sherin, 2002), we suggest that *using* a curriculum can also be educative for teachers. In other words, the process of implementing a new curriculum, can, over time, help teachers to learn new ways of teaching mathematics and to come to new understandings of how their students learn mathematics.

This research has implications for the study of teacher learning, for the design of reform-based curricula, and for teacher education and professional development. First, this study advances our understanding of teacher cognition by offering insights con-

cerning how teachers approach the implementation of reform. In particular, the study reveals that contrasting approaches to curriculum use can occur, even when teachers have similar beliefs about their own ability to implement a new reform-based curriculum. In terms of curriculum development, we suggest that curriculum designers pay attention not only to providing information on specific lessons for teachers, but also to providing broader strategies that teachers can use to implement a new curriculum effectively. For example, are there certain activities that teachers should tend not to omit? And are there particular kinds of adaptations that teachers should consider that would not change the goals of the curriculum? Finally, in terms of professional development, we believe that even veteran teachers can benefit from opportunities to discuss and examine their own approaches to using curriculum, particularly when these materials are reform-based and as such, call for changes in teachers' practices. With appropriate support, perhaps these teachers could have more quickly developed a deep understanding of the curriculum, an understanding that would have allowed them to implement the curriculum with fidelity, while still making appropriate adaptations for their students. In our continued research, we are examining the design of such professional development materials.

## ON THE CHALLENGE OF REFORMING TEACHING: MATHEMATICS TEACHERS AS MEMBERS OF A RHETORICAL COMMUNITY

M. Faaiz Gierdien  
Central Michigan University  
gierd1m@cmich.edu

The post-apartheid South African government's "outcomes-based" educational policy, *Curriculum 2005*, refers to "all learners" which include adults and out-of-school youth as opposed to "students," in warm and reassuring ways. The policy aims to transcend "rigid divisions" such as theory and practice, knowledge and skills, academic and applied knowledge, and education and training (Department of Education, 1997). The mathematics component of this noble policy is called *Mathematical Literacy, Mathematics and Mathematical Sciences* (MLMMS) (see Government Gazette, 1997). Its lengthy name indicates the seriousness with which policymakers view the mentioned dichotomies. This paper focuses on contact points between rhetoric in MLMMS and ways mathematics teachers talk about their teaching. Such a comparison is important because it shows constraints and opportunities teachers face in espousing and enacting reform teaching practices according to MLMMS.

The participants in the study were three middle school and three high school teachers from very diverse school settings in and around Cape Town in the Western Cape. The latter is a province that has the highest success rate in the high-stakes end-of-the-year 12<sup>th</sup> grade examination in South Africa. It is also a province that wants to distance itself from the central government. The participants and the site of the study are therefore interesting in terms of seeing how the central government's ambitious policy statements will unfold at the classroom level.

Literature on educational slogans and slogan systems (Komisar & McClellan, 1961; Scheffler, 1964) enables one to identify habitually repeated phrases and words in policy documents like MLMMS and the NCTM (2000) *Standards*. In particular, this literature allows one to recognize rallying cries of different mathematics education traditions such as constructivism (Steffe & Gale, 1991), ethnomathematics (D'Ambrosio, 1985) and critical mathematics (Skovsmose, 1985; Vithal & Skovsmose, 1997) in policy documents. From here the notion of "policymaker rhetoric" is developed. Likewise teachers in schools form a rhetorical community with a recognizable vocabulary. The participants in the study were interviewed using methods adapted from "A study package for examining and tracking changes in teachers' knowledge" (Kennedy, Ball, & McDiarmid, 1993). Mathematics teachers speak in ways that reveal their knowledge and beliefs about the nature of mathematics, their espouse and enacted models of teaching and learning mathematics, the social context of their work, and their use of texts (Ernest, 1987). On a related point Gregg (1989) refers to the school mathematics tradition (SMT) in which mathematics is viewed as an isolated collection of complex

rules and procedures, teaching is via direct instruction, learning is achieved through rote memorization of rules, and the textbook is the mathematical authority. From the transcribed interviews it was thus possible to identify “teacher rhetoric” which could be either “inside” or beyond the SMT.

Contact points between the teachers’ rhetoric and policy statements come from excerpts in the interview data where I prompted the teachers on rallying cries such as “mathematics as reasoning” and “mathematical connections” which I identified in the “specific outcomes” of MLMMS. The teachers’ responses to these rallying cries serve as evidence of how they react as a “rhetorical community” to similar MLMMS policy statements on reasoning and connections.

Results of the comparison show cases of “similar words and similar understandings” and “similar words and different understandings” between the two sets of rhetoric. There is also the case of the effect of the interview process on the teachers’ rhetoric. The results point to the challenge of bridging lofty and sometimes jargon-laden policy statements and teachers’ rhetoric. In addition, there is the challenge of supporting teachers’ rhetoric with enactment in the classroom, implying the “creation of a rich conversation, in and around classrooms, about mathematics, teaching and learning” (Cohen & Ball, 1990, p. 337).

The efforts of the past decade to improve precollege mathematics education have placed increasing demands on undergraduate programs to supply a strong cadre of teachers prepared to sustain these efforts and to help prepare all students to meet the technological demands of the 21st century. Research suggests that the undergraduate experience is critical in the development of prospective mathematics teachers (Fisher & Leitzel, 1997; National Research Council, 1996; National Science Foundation, 1996). The recent report from the RAND Mathematics Study Panel (2002) proposes a direction for further research.

At the same time, more needs to be learned about the mathematical resources needed for teaching. Measures developed can only be as good as the conceptions of what needs to be measured. We propose systematic analytic and empirical work on what mathematical knowledge is needed in order to teach, and how it is deployed in the course of teaching for what sorts of tasks. (p. 66)

It has been suggested that throughout the undergraduate experience, prospective teachers need the opportunity to explore the connections between the mathematics they are studying and the school mathematics they will be teaching (Fisher & Leitzel, 1997).

This paper is the result of a pilot study designed to explore how prospective teachers of mathematics develop an understanding of undergraduate mathematics. In particular, we examined how prospective teachers' knowledge of mathematics develops in the context of curricula designed to facilitate students' connections between two content areas of undergraduate mathematics. The context for the study was an undergraduate course in geometry required of prospective mathematics teachers. During the course a set of undergraduate curriculum modules were developed and implemented (funding for the project is provided by NSF-DUE CLLI Grant #9981029). The modules provided the students the opportunity to make connections between the mathematical content areas of transformational geometry, linear algebra and abstract algebra.

Ball (1991) states that "although something called 'subject matter knowledge' is widely acknowledged as a central component of what mathematics teachers need to know, little agreement exists about what this means or how to tell whether teachers have it" (p. 82). She suggests that the traditional means of measuring understand-

ing, “course work, grades, and test scores,” are not sufficient and that a change in the outcomes of school mathematics will depend in part “on closer and more serious consideration of the mathematics that the teachers need to understand, as well as how, when, and where they can acquire this kind of understanding and how we can assess it” (p. 82). This project provided a context within which to investigate the following question related to Ball’s comments: What are the characteristics of a prospective teacher’s understanding of undergraduate mathematics in the context of this integrative experience?

Integrated units in transformational geometry and linear algebra provided the context for the investigation of the above research question related to the development of prospective teachers’ mathematical understanding. The materials were implemented in a junior level undergraduate geometry course in the fall semester 2002. There were twenty students enrolled in the course. Results reported here are products of journal entry and interview data. Three interviews were conducted during the course of the semester and the interviews focused on the students’ beliefs about mathematics, understandings of mathematics, and the connections they were developing between the content areas of mathematics and between precollege and college mathematics.

Interview transcripts were analyzed using open and selective coding techniques (Strauss & Corbin, 1998). Theories of Sfard (1991), Dubinsky (1991), and Tall, Thomas, Davis, Gray, & Simpson (2000) informed the data analysis. In particular, Tall and colleagues (2000) discuss various theories which describe students’ transition from viewing mathematical ideas as processes to viewing them as objects. These transitions are sometimes called “encapsulation” (Dubinsky) or “reification” (Sfard).

Tall et al. (2000) also discuss the difference between students’ *perceived* geometric objects (drawings, etc.) and *conceived* geometric objects (mind’s eye, uniform, etc.). They state “...the construction of perceived geometric objects leads later to conceived geometric objects, which, though, imagined in the mind’s eye, and discussed verbally between individuals, are perfect entities that have no real-world equivalent” (p. 236). Student’s views of geometric ideas may influence their abilities to reason geometrically and data from this study has shown evidence of two such instances.

Students in this study first saw transformations as processes that map geometric objects onto other geometric objects. Data analysis suggests that students viewed transformations as processes but had difficulty utilizing them in geometric proof. Evidence indicates that students are seeing transformations as acting on perceived objects and that this inhibits their ability to construct geometric proofs using transformations. The curriculum in this study treated transformations as objects that carried a group structure. Data analysis suggests students had difficulty viewing transformations as a group. Evidence suggests that students’ views of transformations as processes, not as objects, caused them difficulty in seeing the inherent group structure. There is also evidence that indicates students had not encapsulated, or reified, transformations and therefore had not begun to view them as objects.

This research supports the view that in geometry students' encapsulation of mathematical ideas as objects may be supportive to their mathematical understanding. In the context of this study the following questions arise that form the basis for future data analysis and research: Were students seeing transformations as processes that acted on perceived objects or processes that acted on conceived objects? What role might these views play in a student's ability to construct geometric proofs? In geometry what might enhance student transition from working with perceived to working with conceived objects? What experiences might enhance students' abilities to encapsulate the mathematical idea of transformations?

**TEACHERS' NUMBER SENSE: ITS INFLUENCE  
ON TEACHING**

Norene Vail Lowery  
University of Houston  
nlowery@uh.edu

Rena M. Shull  
University of Houston  
renashull@msn.com

Studies have focused on the development of number sense in children, but studies involving adults are scarce, if not, non-existent. Unfortunately, elementary teachers are often among those that do not possess a good sense of number. If reform is to be successful and if all students are to achieve success in mathematics, teachers must possess a good sense of number. How can teachers foster number sense development in students if teachers do not understand what number sense is? Studies addressing how the number sense development of teachers may affect the number sense development of students have not been found. It is vital to research this area to assure competent teachers of elementary school mathematics. This discussion highlights a study involving preservice teachers in an elementary mathematics methods course with a number sense emphasis. The teachers' concept of number sense and that influence on teaching mathematics is investigated within this inquiry.

How do teachers develop number sense in students? Research suggests that activities such as mental computation, estimation, and problem solving discourse (Sowder, 1992) help to foster number sense development. Learning about number and operation is a very complex process (Fuson, 1992). According to the National Council of Teachers of Mathematics' (NCTM) (NCTM, 2000) "...understanding number and operations, developing number sense, and gaining fluency in arithmetic computation form the core of mathematics education for the elementary grades" (p. 32). This must progress into a fully developed sense of number in high school students. The development of number sense does not always occur in this manner. Teachers bring prior experiences and understandings that profoundly shape their learning (Ball, 1996). From these experiences teachers have formed ideas about their role as a mathematics teacher, about who can learn mathematics, and about what it takes to learn and know mathematics. Elementary teachers are the products of the very system they are now trying to reform.

How number sense develops is unclear. Sowder (1992) investigated components of number sense and how they are exhibited: numeration, number magnitude, mental computation, and computational estimation. A richness of student involvement activities provides positive effects versus the negative effects of emphasis on calculations. Shull (1998) investigated the development of number sense in students over a three-year time period in which one essential indicator of number sense appeared to be the ability to generalize. Results from a direct instruction and number sense inquiry (Markovits & Sowder, 1994) indicate that students had reorganized existing knowledge

rather than learned new knowledge. Instruction emphasized conceptual knowledge and allowed the students to make connections between prior knowledge and new knowledge. Curriculum and instruction that incorporate a constructivist approach to learning (learner-centered) have a greater potential to offer learning opportunities for developing a sense of number. Students need to develop good number sense to be effective problem solvers. Efforts must be made in the classroom to help students make connections between what they know about numbers and what they know about operations on numbers. Since number sense is not a set of isolated facts, it cannot be assessed just by written paper-and-pencil tests. Sowder (1989) believes that number sense must be assessed in a non-traditional manner. Alternative forms of assessment are warranted.

### **The Context**

A course goal was to develop understanding of mathematical concepts in a non-algorithmic way and to foster the development of numbers sense in teachers. A standards-based, constructivist approach to instruction was implemented. Mental computation exercises were conducted regularly in class. A timed, written number sense test, a mental math test were administered that served as a pretest/posttest assessment along with a free-response questionnaire. Data were collected from three different methods classes, part of a field-based program in southeast Texas. Questions on the 45-item test were developed using the Framework for Examining Basic Numbers Sense (McIntosh, Reys, & Reys, 1992). The majority of teachers' number sense, as measured by the number sense test, seems to be the same. Two or three points in either direction were interpreted to being the same score. A few students seemed to demonstrate a high level of change (40% increase) and others decreased. An item analysis was performed. The results were mixed. The exit assessment (four multi-level, free-response questions) assessed the level of teachers' number sense after receiving instructional strategy sessions. It was assumed that if the teacher displayed the ability to generalize, then this may be an indicator of number sense held. This would reinforce previous findings (Shull, 1998). Data were collected and analyzed for accuracy and completion of response. Responses were rated as high, medium, and low according to displayed level of accuracy and comprehension. Results were mixed and preliminary results are inconclusive. However, further examination, analysis, and re-investigation is warranted.

### **Discussion**

It was questioned if teachers' perception of number sense could affect the development of number sense in students. This discussion reviews an inquiry into the number sense of elementary teachers and the possible relation with teaching elementary mathematics and student development of number sense and mathematical understanding.

Many factors may have been critical in the results obtained. The profile of the

teachers reveal that most hold interest in early childhood or language arts (not mathematics) and that many have English as a second language. These factors and the time-constraint factor of the testing should be examined in more detail before proceeding with further reporting and analysis of data. Preliminary results from data collected from the pretest and posttest mental math instrument indicate some growth in number sense ability is possible. Future inquiry and treatment plans include more emphasis on mental math and the development of number sense with qualitative measures such as, "What is number sense?". Research investigating and developing number sense in pre-service teachers is sparse. Instruction on estimation and mental computation provides an avenue for developing number sense in students (Sowder, 1992). Implementing this research into the practice of preservice teacher instruction in methods courses is necessary. Number sense is believed to be the ability to think on one's feet. It is crucial that elementary teachers have a strong, solid sense of number to successfully provide curricula, instruction, and assessment that foster number sense growth in students. From this study, data provide some insight into the deficiency, strength, and growth of number sense and indicate need for further study.

## **ELEMENTARY TEACHER STUDENTS' MATHEMATICAL UNDERSTANDING EXPLAINED VIA CONCEPTUAL CHANGE**

Kaarina Merenluoto  
University of Turku  
kaamer@utu.fi

Erkki Pehkonen,  
University of Turku  
erkki.pehkonen@utu.fi

In Finland the elementary teachers are responsible for mathematics teaching to children during their first six years of schooling. They teach the basic mathematical basic skills and moreover, during those years they also build a basis for children's future attitudes toward mathematics. Some professors of mathematics consider that these first years of school mathematics, however, give a weak basis for all future mathematics instruction due to the low level of mathematical skills of the elementary teachers themselves (cf. Martio 1998; Pehkonen 1999). In this elementary teacher students' mathematical skills and understanding is discussed.

In learning mathematics, every extension to the number concept demands, not only accepting new concepts, but new ways of thinking as well. This new thinking more or less contradicts the prior fundamental logic of natural numbers (Merenluoto, 2001). Therefore, misconceptions and learning difficulties are possible at every enlargement of number domains. The very fundamental idea of successor, for example, is necessary for learning the notion of natural numbers. It is, however, seriously conflicting with the understanding of the very character of both rational and real numbers (Sowder, 1992). In the domains of rational and real numbers, the principle of successor is not defined but in every interval infinite successive division is possible. This quality makes the sorting of these numbers difficult, because the students' are prone to use their knowledge of whole numbers in the process. Understanding the successive division demands intuition on infinite processes which, however, in students' thinking seems to be dominated by the finite processes of everyday thinking (Merenluoto, 2001).

According to the theories on conceptual change (cf. Carey, 1985; Vosniadou, Ioannides, Dimitrakopoulou, & Papademetriou, 2001) the relationship between learners' prior knowledge and new information to be learned is one of the most crucial factors in determining the quality of learning. Researchers make a distinction between two levels of difficulty in the learning process targeted at conceptual change: a continuous growth and a discontinuous change. In this distinction the easier level of conceptual change is called enrichment kind of learning, suggesting continuous growth or improving the existing knowledge structure. The more difficult conceptual change is needed when the prior knowledge is not incompatible with the new information but needs revision.

## Objectives and Methods

The aim of this paper is to analyze the elementary teacher students' mathematical skills and their understanding of school mathematics. Furthermore, we try to explain the results obtained from the viewpoint of theories of conceptual change.

In November 2000, elementary teacher students' basic skills and understanding in school mathematics were measured with a level test in the Department of Teacher Education at the University of Turku (Finland). New teacher students' skills in elementary school mathematics (i.e., in grades 1–6) were decided to check with the level test. The aim of this test was to filter those few students who might possibly still have difficulties in some parts of elementary school mathematics. Most of the first year elementary teacher students ( $n = 70$ ; i.e., 88% of all) participated the level test.

The level test was composed of two different parts: In the first part, there were ten simple mechanical tasks with one correct solution. They are similar to tasks to be found in every elementary mathematics textbook. In the second part, there were six open tasks with several solutions. Such tasks are rare in school textbooks. All tasks in both parts can be solved with elementary school (i.e., grades 1–6) mathematics.

## Results

The results from the level test refer to serious problems in elementary teachers' number concept. All ten tasks of the mechanical part of the level test were correctly solved by less than one third of the students (29%). Less than half of the students (48%) received the result needed for passing the level test (at least nine tasks correctly). In the six problem tasks of the level test, the students had remarkably more difficulties. The mean score in the first part was 77% and in the second part 45%, the difference between them was statistically significant ( $F(1, 69) = 134.82$ ;  $p < .001$ ).

When considering the amount of correct answers, almost everybody has the tasks done correctly, when using whole numbers. But in the tasks demanding skills in fractions and decimal numbers, about three fourths of the students (76%) were successful. The most difficult task was to find the decimal presentation for  $5/17$ , where many students divided 17 with 5. The difficulties the subjects had in handling fractions and decimal numbers, refer to serious deficiencies in their number concept.

Problems with rational numbers were especially obvious in the task, where the concept of successor was embedded. For example, the results of task 13 (from the second part of the level test) *"Try to find out which would be the biggest fraction which is still smaller than 3. Give reasons for you answer!"* describe the situation clearly: The task was unanswered by one-fifth of the students (21%), and a clear "one smaller" method of the whole numbers was used by one-fifth (19%). Only one-tenth of the respondents (11%) wrote clearly the correct answer that there is no such number.

Especially in the problem tasks the results refer to a low level of mathematical thinking and to the restrictive nature of thinking based on whole numbers. Task 11

(from the second part of the level test) "*a) Find out numbers in the empty places in such a way that the calculation is valid:  $(\_\_ + 12) : 3 - \_\_ = 5$ . b) Do you find another solution? c) How many solutions do you think that there exist?*" deals with unlimited amount of solutions. Here, about one-fourth (24%) found correctly two alternative solutions and recognized that there are even more, but noted carefully to it with words like "many" or "several". Almost one-third of the students (27%) had an idea of unbounded, uncounted or infinite number of solutions, but they were not able to reason their answer. Only two students (of 70) presented a high-level solution where the infinite number of the solutions was based on the relation between the unknown variables, and where the numbers used were not restricted to positive whole numbers.

### Discussion

The results refer to serious problems in the numbers concept, and to a low level of mathematical thinking of almost all the elementary teacher students. The results also suggest that the use of whole numbers and everyday experiences dominates their thinking. Thus it is possible that the difficulties the students had refer to problems of conceptual change in their number concept. Further it is also an indication that the extension of the number domains has not been dealt with thoroughly enough from a theoretical viewpoint, but teachers have rushed into practice with new numbers.

Within the theories of conceptual change, it has been recently emphasized that, the prior knowledge is can be very resistant to teaching, and that the process of a radical change can be very slow, and that the students' are easily prone to 'fall back' to their previous thinking. It is possible that most of the students were not even aware of the need to reconsider their initial thinking on numbers.

In teaching of school mathematics, these problems should be recognized, and the construction of students' number structure needs to be supported. One of the presumptions for the conceptual change is the ability for meta-conceptual awareness of one's thinking. It is suggested that the elementary teacher program could benefit from consideration of the viewpoints of conceptual change.

Janine T. Remillard  
University of Pennsylvania  
janiner@gse.upenn.edu

This paper examines the teaching practices of a first-grade teacher who was uncomfortable with mathematics and who identified herself as a “weak” mathematics teacher. In other respects, Ms. Jones was considered an exemplary teacher. In particular, she enjoyed teaching reading and was skilled at engaging her students in authentic and interactive activities related to literacy. Given the discontinuities between her views of mathematics and literacy, this study aimed to examine and compare her practices in these two areas. During this study, Ms. Jones used a reform-oriented curriculum, *Investigations in Numbers, Data, and Space* (TERC, 1998) for the first time and participated in regular mathematics study group meetings. Ms. Jones’ feelings about mathematics and literacy were typical of many elementary teachers confronting mathematics education reform (Ball, 1994). Understanding what resources she drew on in navigating this new terrain as well as what challenges she faced can offer insights into what is involved in supporting teachers as they attempt to change their mathematics teaching practices.

### Theoretical Framework

Many have argued that teachers’ mathematical knowledge (Ball, 1994; Heaton, 1992) and beliefs about mathematics, teaching, and learning (Smith, 1996; Thompson, 1992) significantly influence their practices. Thompson, for example, argues that teachers’ beliefs about mathematics and the pedagogy associated with its teaching “play a significant role in shaping the teachers’ characteristic patterns of instructional behavior” (p. 130). For example, teachers who view mathematics as a body of rules and procedures, tend to emphasize this conception in their teaching (Remillard, 1999, Thompson, 1992). The depth and nature of a teacher’s mathematical knowledge is viewed as integrally connected to her beliefs and practice (Wilson, Shulman, & Richert, 1987).

This depth of knowledge is critical for teachers aiming to respond to current reform efforts in mathematics education that emphasize conceptual understanding, reasoning and problem-solving. Such practices place significant organizational and intellectual demands on any teacher (Ball, 1994). For teachers who lack mathematical knowledge, engaging in such practices can be intimidating. Studies have documented teachers’ attempts to use new curriculum materials or experiment with reform-inspired practices that have resulted in mathematically problematic teaching (Cahnmann & Remillard, in press; Heaton, 1992). As these authors argue, helping students learn to think mathematically is challenging work that cannot be prescribed in a teacher’s guide.

What does this mean for elementary teachers who teach many subjects? Can pedagogical knowledge developed in one subject area contribute to that in others? Flick (1995) studied an elementary school teacher whose scientific content knowledge was weak, but who readily engaged students in inquiry-based reading instruction. These well developed pedagogical skills served as "assets in negotiating the rapid flow of relatively unstructured information typical of inquiry in elementary classrooms" (p. 1065). In contrast, Spillane (1995) documented a case of an elementary teacher whose ability to facilitate inquiry-oriented discussion amongst her fifth graders in the area of literacy was cut short when it came to mathematics. He argued that "subject-matter is a critical variable in understanding teachers' efforts to reconstruct their teaching" (p. 44). In the current study, we explored when and how a teacher's pedagogical practices might transcend subject areas and serve as resources in the development of others.

### Methods/Data Sources

This study is part of a larger study examining teacher learning, classroom practices, and student learning in urban schools. We examined one year in a first grade classroom in an urban elementary school in which all 30 students in the class were African-American and many were from low-income families.

The data were based on about 40 hours of classroom observations of the teacher's mathematics and reading teaching and 4 formal tape-recorded interviews. We also had a number of informal discussions and correspondences with her. The interviews were open-ended with guiding questions that included, but were not limited to, beliefs about teaching and mathematics and pedagogical practices. Analysis began by using field notes to characterize and then compare the teacher's practices in mathematics and literacy. In order to explain the patterns and contrasts, we coded transcripts of the interviews and analyzed them according to emergent and predetermined themes.

### Results

Our analyses of the patterns in Ms. Jones' pedagogical practices during reading instruction as well as mathematics revealed several notable practices that seemed to transcend subject matters. These include a) a deep commitment to highly interactive lessons that included significant student participation and interaction, b) an appreciation of student-student interaction during instruction, and c) the inclination to make connections to previous lessons.

One distinction we noted between Ms. Jones' reading and mathematics lessons was in the level of flexibility she brought to the subject. In reading, she frequently veered from her plans to follow the lead of a student or to make connections to other student experiences. In one instance, when a student observed rhyming words, Ms. Jones turned the conversation to an exploration of rhyming words and sounds. At other times, she encouraged students to find relationships between events discussed in science or elsewhere and the content of the reading lesson.

Ms. Jones identified the ability to respond to students spontaneously and to take advantage of their observations and insights as a critical component of her teaching. "I think spontaneous is much better because I think you're teaching to...with the children, rather than just 'ok, . . .this is what comes next'" (Interview, 3-2-02). She was highly conscious of the fact that she was not comfortable making spontaneous changes in her mathematics lessons. As she put it, "I don't feel secure enough about that at all to just be spontaneous" (Interview, 3-2-02). Indeed, during each of the mathematics lessons we observed, Ms. Jones designed a lesson using an activity in the *Investigations* curriculum and then followed her plans rigidly. Her discomfort with responding to students spontaneously was also evident in a pattern we observed in her selection of suggestions from the curriculum; she rarely brought her students back together after an activity to attempt a class discussion—a suggestion that occurs frequently in the curriculum.

It is evident that her strong pedagogical skills in reading, the availability of a reform-oriented curriculum guide, and classroom support were not enough to help Ms. Jones overcome her discomfort related to teaching mathematics. In fact, her discomfort formed a formidable barrier to her efforts to teach mathematics for meaning. Throughout the year, she admitted that mathematics was the first subject to be dropped from her often-packed schedule. We noticed this tendency increased as the year progressed.

In endeavoring to explain the difficulties Ms. Jones had teaching mathematics, we sought to go beyond the claim that she had limited knowledge of mathematics necessary to develop mathematical pedagogical content knowledge (Wilson, et al., 1987). The knowledge gaps that appeared most significant in inhibiting her efforts were related to her understanding of the purposes underlying the activities in the curriculum and their connections to the mathematics she thought her students needed to learn. In several conversations, Ms. Jones stated that she was concerned that her students were not learning basic facts and that she felt unsure how to respond to parents' concerns about the mathematics she was teaching. Interestingly, the conflicts that Ms. Jones felt led her to avoid teaching mathematics, rather than supplement with other material.

### Conclusion

It is our view that Ms. Jones' generic pedagogical strategies were critical for helping her experiment with unfamiliar approaches to teaching mathematics. However, they were not enough to help her interpret the ideas in the curriculum and connect them to what she understood about mathematics. While it is evident that Ms. Jones would benefit from a deeper understanding of mathematics, we argue that her needs were specific to her curriculum. Her case illustrates difficulties that arise when teachers use reform-oriented curricula. It also suggests the potential for deepening teachers' mathematical knowledge within the context of exploring new curriculum materials.

## **AN EXAMINATION OF THE KNOWLEDGE BASE FOR TEACHING AMONG UNIVERSITY MATHEMATICS FACULTY TEACHING CALCULUS**

Kimberly B. Santucci, Thomas C. DeFranco & Jean McGivney-Burelle  
University of Connecticut Mathematics Education Research Group (MERG)  
kimtucci@yahoo.com

This poster session will report on a dissertation research study designed to examine teacher knowledge base (TKB) among university mathematics faculty. Research on TKB at the K-12 level provides a solid foundation for exploring related issues in post-secondary education. This study seeks to uncover the categories and components that constitute a framework for TKB in undergraduate mathematics, identify themes that exist in the TKB of university mathematics faculty, and examine issues of consistency between the TKB of university mathematics faculty and their instructional practice. Preliminary results and implications for future research will be addressed.

### **Teacher Knowledge Base**

Several national mathematical organizations (National Research Council, 1991; National Science Foundation, 1996) have declared a "state of crisis" in undergraduate mathematics education and have recommended that researchers focus more attention on the teaching and learning of undergraduate mathematics. Research (Fennema & Franke, 1992), nearly exclusive to the K-12 level, has shown that one's "knowledge base for teaching" has the most significant influence on his or her instructional practice. What types of knowledge are needed for teaching mathematics and how teachers utilize their knowledge base to inform their instructional reasoning and action are both compelling questions (Wilson, Shulman, & Richert, 1987). Shulman (1987) articulated a framework of TKB that included knowledge of content, context, general pedagogy, curriculum, learners, educational ends and pedagogical content. Considerable research has been conducted in this area, yet existing models of TKB still need to be refined.

This study extends this line of investigation to the undergraduate calculus classroom. A framework of the knowledge base for teaching undergraduate mathematics (beliefs, context specific knowledge, general pedagogical knowledge, personal practical knowledge, the nature of disciplinary mathematical knowledge, and knowledge of research) was developed and piloted. The purpose of this research is to investigate TKB among university mathematics faculty and examine the nature of its consistency with their instructional practice. Themes and patterns that exist related to TKB among university mathematics faculty will be identified and will provide a foundation for future research aimed at reform in the teaching and learning of undergraduate mathematics.

Eight university mathematics faculty from four-year institutions will be interviewed, observed, and video-taped. Interview data will be coded and sorted to identify

existing themes, which will be entered into a text matrix for within- and cross-case analyses. Classroom observation field notes will allow for representative segments of the participant's instructional practice to be identified. A representative video lesson segment will be analyzed using a coding scheme adapted from the research (Brenderfur & Frykholm, 2000; Schoenfeld, 1998; Wells, 2002). This model will be used to analyze classroom instruction, including the mathematical discourse evident, at a microscopic level to explain how the knowledge, beliefs, goals and images of the teacher combine to produce his or her actions in the classroom. Preliminary results from this research are forthcoming and will be reported in the poster session.
